Four Copies \$5.—Single Number, 15 Cents.

VOLUME XXXIX.—No. 1.

NEW YORK, JANUARY, 1880.

NEW SERIES—No. 396.

THE FARMER'S NEW YEAR'S CALLERS.—DRAWN BY R. E. ROBINSON.

Birds in winter are always welcome. Perhaps we notice them more readily when the whole landscape is covered with snow; their quick motions bring life to the profound quiet, and their chirpings seem like music in the noiseless winter morning. Even a few Chieadees and common Snow-birds are welcome, for their quick and pleasing motions, but when the north wind brings down a whole flock of Snow Buntings, then there is life in earnest. Our farmer artist, to whom we are indebted for many drawings of birds from life, gives us a view of a

visit of the Snow Buntings, which he entitles "The Farmer's New Year's Callers." The Snow Bunting, or Snow-flake, is found throughout the Arctic circle, and comes down to us only in winter, being quite frequent along our northern border, and sometimes reaches as far south as Maryland. The birds fly in large and compact flocks, and as they often come before driving winds and sweeping snow-storms, their appearance is regarded as the forerunner of severe weather. Being deprived of nearly all food in their northern home, their journey southward is apparently one of necessity; they do not remain long at any place until they reach the vicinity of the sea-coast, where, in the salt marshes, they become very fat. Inland they appear to be very unsettled and impatient; they sometimes settle in large numbers near the house, alighting on fences and bushes, or in the yards and roads, actively seeking food. It is an act of kindness to do as our farmer is doing, and welcome the callers with a bit of cheer. The bird comes to us in its winter dress,

in which white predominates, with cloudings of brown, and occasionally the back, wings, and tail, variegated with black. It is sometimes called the "White Snow-bird," to distinguish it from the more frequent winter visitor. The Snow Bunting, while it feeds mainly upon seeds, is very fond of small shell fish, frequenting both fresh and salt marshes in search of these. Aside from the pleasure they afford to those who welcome them as imparting life to the winter scene, others take a different view of them, and consider their value by the dozen in the market. After they have been in our latitude, especially if near the coast, for a short time, they become very fat, and are regarded as most delicate eating; they are often sold in our markets as "Ortolans." They often fly in such dense masses, that they are shot in great numbers; and many are also taken in traps. In Northern Europe the coming of these birds is a great event for the poorer classes, as it allows them to have a time of feasting. In some European countries they are caught and fattened for the table, and in far northern countries they are dried for future use.

## Hints for the Work of the Month.

[The Hints and Suggestions in these columns are never copied from previous years, but are freshly prepared for every month, from the latest experience and observations, by practical men in each department.]

**How do You Stand?**—One cannot lay out his work to advantage, without knowing precisely how he stands with regard to his business. The beginning of the year is the appropriate time for ascertaining it. Frequently an account of business is kept for a month or two, and then neglected. If it is only to encourage habits of regularity and perseverance, it will be time well spent to keep an account, not only of money affairs, but a record of events for every day. This tends to beget promptness and system in every detail of farm work, and in business affairs, that foresight and economy which are everywhere the prime essentials to success.

**Keep a Record** of the events of each day's work, and farm-life. One of the boys or girls should do this. A book will be needed, ruled with plain lines, on which to make the entries; put down the condition of the weather, the work done, and by whom; purchases and sales made, indeed, anything that may be needed for future reference, or that should be entered in the account book, which will thus become a valuable and interesting record of the farm.

**Make an Inventory**—Put down every thing you possess, from the farm itself, to the small tools and utensils, and value each item fairly. Enter the money on hand, and also every debt owed. This is the first work in beginning an account. The property owned, and money on hand, will be on one side of the account, and the debts on the other. The balance will show just how the farmer stands. This account will be the *Account of Stock*.

**Purchases and Sales**, are entered in the daily record, and from that into a purchase and sale book; except the cash transactions, which go into the cash book.

**The Cash Book**.—Every payment and receipt of money for purchases, sales, or for wages, should be entered in the cash book; this should be done every evening, and before it is forgotten; all these entries are transferred to a ledger to the proper accounts. The work is very simple and easy, and there are farmer's girls who keep all their father's accounts in the most accurate manner. Fuller directions for keeping farm accounts, were given in the *American*

*Agriculturist* for January and February, 1879.

**Hiring Men**.—A farmer should try to make work for a hired man, or several if possible. If he can find profitable work for them, he is making money for himself. A few months wages spent in procuring or making manure, draining, clearing off stone, getting out stumps, or otherwise making the farm more productive, will be well invested.

**Keep the Stables Clean**; clear out the manure every morning, and scrape or card off all filth from the animals. The stable should be made so warm, that the manure will not freeze at night; a lower temperature will either demand a larger amount of food, or the animals will fall off in condition.

**Pile the Manure** in square and compact heaps; and if it is not frozen when thrown out, it will heat and ferment in the pile; but if once frozen, it will be likely to remain so during all the cold weather.

**In the Southern States**, the work of making compost heaps, should go on rapidly this month. Time is needed in making composts; raw mixtures are not fit for fertilizers, until the materials are decomposed. A bushel of lime added to each load, will hasten the decay of the materials of the compost heap, and cotton seed, well soaked with water will soon heat, and warm up a large pile of compost.

**Cut the Litter**.—If the litter is cut into 3-inch lengths, or even smaller, it will hold more moisture, will make better and finer manure, and will keep the animals cleaner than long litter. The gain in the quality of the manure, in one year, the saving in time in the handling, and increased effectiveness of it, will pay good interest on the cost of a windmill, and a fodder cutter, to do the cutting. But if the stormy and disagreeable days are chosen to cut up straw for this purpose, an abundant supply can be made. A broad axe can be purchased for \$2.50, and with this and a block, a sheaf of straw may be cut into 3-inch chaff, in half a minute. Two persons, one to hold the sheaf on the block or plank, and the other to use the axe, would soon cut up a ton of straw. Where hard-wood saw-dust, dry swamp muck, or pine straw can be procured, these make excellent litter and manure.

**Economy in Feeding**, is a very important consideration. In some cases half the feed used is wasted. Cutting the fodder has proved a saving of one-third to one-half. Where but 10 head of stock are fed, if the feed of one-third or one-half can be saved, it is simply a large increase of the resources of the farm, and is sufficient to pay the cost of a good cutter and the time expended in cutting.

**Watering Stock**.—The supply of water in winter is a source of trouble. Ice gathers about the troughs and other drinking places; pipes freeze and burst, or become choked, and many other inconveniences occur. These may be avoided by methodical management. Have regular watering periods, twice a day. Fill the troughs from the pumps or cisterns, and drive the cattle to them and see that they drink. When all are supplied, empty the troughs, and either cover them or turn them over. Have no flowing water in the yards to waste and freeze, or become ice-cold for drinking. A cold drink will reduce the milk from the cows 10 per cent or more.

**The Milk-Room or Spring-House**.—Frozen cream will not make good butter. To prevent milk from freezing, have a small stove in the dairy, and in the spring-house make a covered box over the spring. Where a run from a spring can be brought in pipes, a Cooley creamery can be used during the winter with great advantage; keeping an even temperature equal to that in the summer when ice is used.

**Horses**.—When not at work the horses need but little grain, if sufficient good hay is given. But as hay is generally dusty, and long hay is wasted in the eating, we find it economical to cut and wet the fodder, and give 3 quarts daily of bran or ground feed. The hay saved will pay for the meal, and the increased value of the manure will pay for the labor. The moist feed prevents injury to the horses from breathing the dust from dry hay.

**Mares in Foal**.—A roomy loose box is the safest and most comfortable place for a brood mare. A colt may be raised for the same cost as a cow, and when 3 years old may be worth four cows. There-

is a brisk demand for good work horses, and a large export business is growing up, so that the keeping of mares will become a source of income. But not only must the right kind be kept, and the right kind of colts be raised, but the mares must have proper stable accommodations. When a mare is idle a large portion of the time, exercise is needed, and this she can get in a loose box.

**Colts.**—Young colts should be well fed and cared for the first winter; provide a warm stall for them, with plenty of litter, and give them a good brushing down once every day. A quart of oats, daily, will be needed, and some bright, clean, sweet hay. Cut-feed is not suitable for young colts, whose digestion should not be overtaxed by food packed solidly in the stomach; feed light and frequently.

**Work Oxen.**—Oxen that work on frozen roads, although there is no ice, should be shod. The rough, hard surface wears down the hoofs very fast, and causes inflammation of the interior; the trouble may not become apparent until later, when the mischief is difficult to repair. If the feet are tender and hot, and slight lameness is perceived, examine the hoofs between the claws, cleanse the feet, and apply remedies if needed.

**Cows.**—Milking cows will be benefited by mixing their feed with warm water, if this can be done without too much trouble. A family cow may be treated to a warm mess in the mornings without difficulty, and it will increase the milk perceptibly. Cut the hay and pour a pailful of hot water over it; mix the mess so that the hay is all wetted, and add the meal; mix again, and feed while warm. In a dairy of 20 cows, the extra milk will pay for the labor needed. If the food can be made more digestible, and by giving it warm, the waste of animal heat will be avoided, and the same effect will result as from an increase of food. Thus the study of the principles of feeding may be made a source of profit by the economy which may be practised through it. The card and brush should be in frequent use during the winter, and if necessary a coarse cloth and warm water may be used to preserve cleanliness. If filth is permitted to gather on the skin it is difficult to remove at this season.

**Young Calves** will thrive well if kept in a shed together and well fed. The shed may be littered liberally, and need not be cleaned out until the spring, or until the manure has become a foot or more deep. Calves may thus become good manure-makers, but it will be necessary to feed them well. Bran and oats, with a little corn, will be the best food for them. Give one pint a day for those under a year, and a quart or two daily for yearlings. Costiveness in cold weather should be carefully guarded against, and, if necessary, half a pint of raw linseed-oil, or a pint of linseed-meal, should be given with the food as a remedy.

**Sheep.**—A flock of sheep may be made the most profitable of farm stock, both in return of money and of manure. By feeding a small flock well, through the winter, their value may be easily doubled. But the feeding should be liberal and the care unremitting. The chief requisites for success with sheep are, to provide abundant good food and pure well water; to feed and water regularly; to provide fresh pure air, and to avoid dampness. When feeding sheep for market, it is well to try the weights every second week, and note the increase. (For a method of weighing, see *American Agriculturist* for Dec., 1879, page 500.) The effects of the feeding can thus be readily ascertained and changes made if it is thought necessary.

**Breeding Ewes** that are expected to drop lambs early, should be closely watched. The springing of the udder is an unfailing sign of approaching parturition. The ewe should then be removed to a separate pen and kept quiet, but visited at least every three hours and the last thing at night. It is rarely that any help is needed, except, in very cold weather, to wrap a piece of soft blanket about the lamb and to help it to suck as soon as possible. As soon as the lamb gets a meal it will be all right, and the ewe may be left to herself for a few hours.

**Tameness and Gentleness** are qualities to be encouraged in all domestic animals. Their value is

discovered when it is necessary to handle the animals at critical periods. When confidence, if not affection, exists, one can do much with a suffering animal, when otherwise interference might make matters worse. It would be well to make friends with cows, and sheep, especially, by petting them, giving them salt and palatable things, and mingling with them in the yards. Every animal should be trained to be handled when loose in the yard.

**Lambs.**—Lambs dropped this month should be well fed through the ewe. Give little heating food, such as corn, in any shape; but bran, oil-cake meal, and oatmeal in gruel, will be healthful and nourishing for the ewe and the lamb. In stormy weather the ewe and lamb may be kept under cover, but in fine, sunny days, they may run in a dry yard; but not with other sheep. Early lambs for market should be pushed ahead as fast as may be safe.

**Pigs.**—Store pigs will thrive well on roots with a slop of bran, sour milk and water. A supply of roots on hand will greatly reduce the cost of feeding store pigs. Turnips that can not well be fed to cows may be given to the pigs. Give young pigs a warm dry bed.

**Lice.**—The irritation of lice keeps young animals poor and miserable. To rid them of these pests, brush the skin all over thoroughly with a brush dipped in a mixture of linseed-oil and kerosene, shaking the excess of oil out before using the brush. Work the grease down to the skin; if this is persevered in the lice will soon disappear.

**Poultry.**—Hens and early pullets will now be laying freely. They should be encouraged by giving them warm food. Baked small potatoes taken direct from the oven, and hot, are much relished by the fowls; scalded corn-meal, corn or wheat parched in the oven, crusts of bread, or oatmeal, steeped in hot milk; and meat scraps, with some stimulating condiment, like Cayenne pepper, will be found to add greatly to the store of eggs all through the stormiest weather; but the fowls must have a dry, warm, clean, sheltered place to roost and lay in.

**Ice.**—Get in a supply of ice as early as possible. A stock in the house is worth two in the pond. A supply has often been missed by waiting one day too long. When ice is 6 or 8 inches thick, it should be cut and stored without delay. See article on Ice-houses in *American Agriculturist* for Dec., 1879.

### Notes on Orchard and Garden Work.

The opening of a new year brings many new readers, and a word to these is here in place. It should be understood that these Notes are not written for the professional horticulturist, or commercial nurseryman; though they may contain valuable information for these, still it is taken for granted that they already possess the necessary knowledge to their business, or can find it in the works belonging to their profession. It is for the amateur that these Notes are written, and by "amateur," we mean every one who does not follow orcharding, or gardening in any of its forms, as an occupation. Farmers as well as others are to be classed as amateurs in these matters, and these Notes are made largely with the view of encouraging farmers in these branches of land culture, and to aid them when they undertake any kind of crops outside of those belonging to the farm proper.

Whoever undertakes an orchard, or fruit growing of any kind, or who has a vegetable garden, or would decorate his grounds with shrubs and flowers, should have at hand a work for reference. To be able to learn a fact, or to remedy a difficulty at once is of great value, and a book will often more than pay for itself in a single reference. We give in the Basket some hints as to the contents of the leading works.

No time is so proper for useful reading as the comparatively leisure days and evenings of winter! It is a foregone conclusion that success cannot be attained in any department of human life without work, and the conclusion is equally clear that the work of the muscles, to be most efficient, must be guided by intelligence; the mind and the hand must labor together to bring about the greatest good.

### Orchard and Nursery.

**An Old Orchard** is as unproductive as it is unsightly, and to one who really loves a tree, many of the orchards one sees in going about the older portions of the country, present melancholy examples of "cruelty to trees." The cause of the present condition of these trees is, partially neglect; mainly robbery. The trees could hardly been brought to their present condition had not the land for these many years been made to bear two crops. The act of planting an orchard is a promise that the trees should be fed. From the very first year these trees have had a yearly crop of grain or hay taken away from their land, except on those where the grass has been taken away by the animals pastured in the orchard. No question is more frequently asked us than

**How to Renovate an Old Orchard?**—There is a "previous question" in this case—"is the orchard worth renovating?" should be first considered. This can not be properly decided by one who has not seen the trees. When trees are very old and badly decayed, with trunks and larger branches more or less hollow, it is not worth while to expend labor upon them; the wood-pile needs them. But if merely badly shaped, and, though sound, are unfruitful, it will generally be a profitable investment to restore them. The

**What to Do**, will vary with circumstances. Often putting down a few rows of drain tiles, with the necessary pruning, will be all that is needed to overcome the original mistake of the planter, who set his trees on land not good enough for the usual farm crops. Many of the bad orchards never could have been good with any above-ground care. If the soil was good, the now suffering trees have been starved. The great want is food; supply it by

**Manuring the Soil.**—Such orchards generally are in grass. Spread a heavy coat of manure over the whole surface, and turn over the sod in the spring. When the sod has decayed, then give a deep plowing, and spread ashes if they can be obtained, or a good dressing of lime, and harrow. Thus far we have attended to the roots. The above-ground portions need care. The trunk and larger branches are usually covered by scales of old bark, growing upon which are mosses and lichens, and hidden beneath them the eggs and chrysalids of insects.

**Scraping the Bark** with a short-handled hoe will remove a portion, but to make a complete job, use strong home-made soft soap, made from ley or potash. Thin this with enough water to apply readily to the bark, and leave the rain to do the rest. Do this work of scraping, etc., early in the spring.

**Pruning** will generally, if not always, be needed. How, and how much, will depend upon the state of each tree. Endeavor to open the tree to let in light and air all through it, and also to bring the head to a well balanced shape. It may require the removal of some large branches and the shortening back of others. This may be done at the end of winter; cover all large wounds with some dark-colored paint. If large ragged wounds have been made by the breaking down of branches, dress the cut by the use of a drawing knife or stout chisel, to make a clean, smooth wound and paint it. We have assumed that the variety of fruit is good. If the tree is sound, but of a worthless variety, renew it by

**Grafting.**—The manner of renewing an old tree by grafting it over to make a new head, must be left until next month's Notes.

**Planting Orchards.**—One contemplating planting an orchard, should first determine to do well by the trees, by giving them the first and sole right to the ground. An orchard poorly kept is a bad investment. Next, use great care in selecting the varieties of fruit. Do not make too long a list.

**Varieties of Apples.**—A dozen varieties is ample, and may be thus divided; two early, four autumn, and six winter kinds. Of course the number in each division will be governed somewhat by individual taste, and whether the fruit is solely for home use or for market. It is difficult to give a list of varieties that will suit all persons and all localities. The following may be of some aid to

those about to make a selection. *Early*—Red Astrachan, Early Harvest, Golden Sweet, Williams' Favorite. *Autumn*—Gravenstein, Porter, Maiden's Blush, Duchess of Oldenburg. *Winter*—Rhode Island Greening, Red Canada, Golden Russet, Ben Davis, Northern Spy.

*Varieties of Peas.*—For orchard planting, the list may be: for *Early*—Doyenne d'Été, Manning's Elizabeth. *Summer*—Bartlett, Clapp's Favorite, Beurre Giffard. *Autumn*—Beurre Hardy, Doyenne Boussock, Seckel, Duchesse d'Angouleme, Belle Lucrative. *Winter*—Winter Nelis, Lawrence, Vicar of Winkfield, Dana's Hovey.

*Peaches.*—In every peach region, the selections for market vary with each locality. The following is a good selection for home use: Early York, Early Crawford, Old Mixon Free, and Smock.

*Cherries.*—Early Richmond, Black Tartarian, Coe's Transparent, are the leading varieties.

*Quinces* are often put in some out of the way, low, wet place, and they often give fair fruit in spite of it; they should have as good soil and culture as any fruit, and when thus treated, few fruits are more profitable. The old Apple or Orange Quince is best known, and good. Rea's Seedling is very fine, and a new Connecticut variety, Champion, gives high promise.

*Purchasing.*—By all means purchase of reliable nurserymen, that you may be sure of good stock, and trees true to name. Other things being equal, it is best to buy as near home as possible, as there is less danger of injury in transportation.

*Insects.*—The clusters of eggs of the Tent Caterpillar are most conspicuous now, and should be found and destroyed. They are always glued in a band near the ends of the small twigs, and are best seen in dull weather.

*Protection.*—Young trees must be secured against the attacks of rabbits by smearing the trunks with blood, or by placing common laths around the trunk, and fastening them in place with wire. In deep snows, mice may work beneath the surface, and gnaw the bark—to prevent this, tread the snow down firmly about the trunk.

*Manure* may be drawn out and spread in the orchard at any time. When the snow is on the ground a sled can be used with advantage, being lower than a wagon, and passing more easily under the trees.

### The Fruit Garden.

For the benefit of the new readers, it may be said that under the "Fruit Garden," we include what are generally known as *small fruits*—the various berries, grapes, dwarf pears, etc. The fruit garden ought to be a reality on every farm, large or small, for the enjoyment it gives, and the health, and even profit which it brings when well cared for—giving a succession of delicious fruits from the time strawberries come until the late grapes are gone. It is an unpleasant fact that the fruit garden is much neglected on many farms. With the good resolutions of the new year, we hope that many will resolve to set apart a portion of ground to be devoted to the culture of small fruits.

*Soil.*—The soil of the fruit garden should be rich and well drained, that it may be loose and allow of a free circulation of air, and not permit water to stand upon or below the surface.

*Manure* of the best quality should be used.

*Strawberries.*—The list is so large that a novice is bewildered in making a selection: Charles Downing, Seth Boyden, Monarch of the West, Duchesse, Forest Rose, and Sharpless, are all good. On heavy soils the old Triomphe de Gand and Jucunda.

*Raspberries.*—Brandywine, Cuthbert, Herstine. *Black Caps.*—Amer. Improved, Mammoth Cluster.

*Gooseberries.*—Downing, Houghton.

*Currents.*—Versailles, White Grape, Red Dutch.

*Blackberries.*—Kittatinny, Snyder, are the best.

*Grapes.*—Concord, Wilder, Delaware, Brighton, Telegraph; Iona and Catawba, where they succeed.

### Kitchen and Market Garden.

This is a department of the *household* and the *farm*—falling under the two heads and joining them

closely together. As is the Kitchen Garden, so is the dinner; and as the dinner, so the health, the disposition, and the general comfort of the household. Aside from the needs of the family table, Kitchen Gardening, in many localities, may be made to pay. If a person is living near a manufacturing town, many things, like cabbages, turnips, green corn, peas, etc., may often be grown and sold with satisfying profit. There are many cases where persons thus engaged have realized greater returns from the garden than from the whole farm. There is nothing *small* in growing peas or cabbages, if they pay better than field corn or wheat. It will pay in many cases to look closely into this matter. It must be borne in mind that, as a general thing, the products of the garden are perishable, and the first condition of success is a near market.

*Manure* is the foundation of good gardening; it is the food out of which plants, as factories, and the sunshine as the force, make the good things for the table. During the winter all the manure, and of the best quality, that is possible, should be made and *saved*. It is one thing to make manure, and another to save it. Be sure and do *both*.

*Leaves* may be collected at any time during the winter when the ground is clear of snow. They make the best of litter, and act as an absorbent of liquid manure, while they are rich themselves.

*Cold Frames.*—It is to be remembered that the plants in the cold frames should not be kept so warm that they start into growth. If such is the case, when a cold snap comes, the young growth is killed down, and the plants ruined. When the temperature is above 30° the sashes should be raised.

*Hot-beds* will be started in the Southern States during this month. At the north the sashes, etc., should be put in order so that everything may be in readiness when the hurrying time of spring comes.

*Roots* put away in trenches will need some additional covering as the cold increases.

*Seeds* should be looked over and a list of those wanted made out and sent to the seedsmen. Order early, and thereby get the better attention.

*Implements.*—See that they are put in good order.

### Flower Garden and Lawn.

The work here will be mostly in preventing injury to the trees and shrubs from heavy snows, and the lawn from being trespassed upon by careless drivers. Evergreens will catch a great amount of snow and bend and break beneath the weight if not relieved; it is best to shake off the snow soon after it falls, while it is loose and light. If the snow is deep, it may be necessary to dig it away from the long, lower limbs of large evergreens. That all persons driving into the grounds in winter may keep in the drives, a number of poles may be set along the roads, and if this is not thought sufficient, a wire may be stretched between them. It is a difficult matter for "fast" people to keep in the right path just after a heavy snow has fallen. The adornment of the surroundings of the house is a subject that most of us will do well to consider. Plan now for new walks and drives. Consider the planting and select the shrubs, herbaceous plants, the flower seeds for annuals, and order early.

### Greenhouse and Window Plants.

This is the season when in-door plants should be showing at their best, and it is the holiday season for the greenhouse, when all without seems lifeless.

*Bulbs* for forcing should be brought out from the cellar, and watered sparingly until they start into new growth.

*Annuals.*—Sow seeds of Candytuft, Sweet Alyssum, Mignonette, and other annuals, for later blooming.

*Insects*, living as they do upon the juices of the plants, are a constant source of injury if not at once removed. The Red Spider may be kept off by thoroughly drenching the foliage, especially on the under surfaces, with water once a week or so. House plants, especially, suffer from the Red Spider, and also from accumulated dust, because their owners think they need "syringing," as usually directed, and this they know is not practicable in

the dwelling room. Syringing is a quick and convenient method of washing the plants, but by no means the only one. Take the plants to the bathtub, lay the pot carefully on its side, and then use the watering-pot, holding it high, so that the fine streams will descend with force, and so direct them that they will strike the undersides of the leaves. Set the plants upright, and let them finish dripping before taking them back to their places. If the bathtub is not at hand, the kitchen-sink will answer as well. The Mealy Bug and Scale may be removed by hand-picking, or by the use of a brush and strong soap-suds. A wash of Tobacco Water is most effectual with the lice, or Green Fly; fumigation with tobacco smoke is used in greenhouses, and allows of wholesale application; this is not so practicable in the house, and tobacco water diligently applied answers as well.

*Worms* in the pots are often a source of serious trouble, but can be removed by turning the ball of earth out of the pot, when the worms will generally be found upon the surface of the ball and may be caught. If *clear* lime-water, enough to saturate the earth, be applied, it will kill the worms, and not injure the plants. An hour or so after applying the lime-water, water abundantly with common water.

*Watering.*—The soil should be kept moist and loose, that there may be a good circulation of air, not alternately soaking wet and powdery dry.

*Window Plants* should have special care when severe weather comes; take them from the window to the middle of the room, and cover with a sheet or other cloth, or with paper during the night.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

**Too Important to be Overlooked.**—While most of the Premium Articles offered by the Publishers are desirable, there is one proposition that demands careful consideration and action, on account of its far-reaching public benefits. We refer to the arrangement for supplying a Circulating Library of few or many Books, agricultural, horticultural, on animals, etc., including also many of the best Standard Works on other subjects. The details of the plan are simply as follows:

*Any ten or more persons, even up to a hundred or more, in any neighborhood or town, can, by uniting and contributing \$1.50 a piece, not only secure the American Agriculturist for each person during 1880, but also as many Dollars' Worth of Books as there are members in the Club or Association. These books, put in charge of one of the members, from time to time, can circulate from one to another until all have read them, and then be kept as a library for reference by all interested. It only needs some enterprising public-spirited person in every town or neighborhood to secure a large valuable collection of books for general use.*

*Even where there are a large number of subscribers already for 1880, there are still remaining enough others to secure quite a library. Of course any person desiring can himself collect the subscriptions, and secure the books as his personal property. Many have done this. It is desirable, however, in this way, to secure a library for public use.*

**For any School, Public or Private,** there is not the slightest doubt that a most valuable and useful acquisition would be a good Compound Microscope. The wonderful revelations of this instrument would awaken great interest on the part of both teachers and pupils, give them a new, now unseen, world of objects to think about, and be very useful in many ways. The high cost and delicate machinery of good instruments of this kind have placed them out of the reach of most ordinary Schools hitherto. The new, most valuable and effective Compound Microscope devised and brought out the past year, and supplied at less than a quarter of the cost of any equally serviceable instrument previously available, puts it within the reach of every school. Several Boards of Public School Trustees have already appropriated the \$10 and purchased one—all others would be warranted in so doing. But it can easily be obtained

by the Teacher or some of the pupils, by getting the sum in subscriptions of 10 cents to \$1 among the patrons. (In most districts, if the patrons of the school were aware of its usefulness, there would be found ten who would contribute \$1.50 each, which would not only secure the Compound Microscope for the School, but also the *American Agriculturist* during 1880, for each one subscribing \$1.50. Or the teacher might collect the subscriptions and receive the instrument himself or herself.)

## The Premiums All Available to Every One This Month.

Every Reader is invited to look over the grand list of Premiums, including no less than \$358 desirable articles of various kinds, besides \$47 choice Books, which include many Standard Works from the leading Publishers. (If any one has not received the Descriptive Premium Sheet, or has it not at hand, he will be supplied by sending a Postal Card request for it.) The Articles and Books offered were secured early last year, before the great rise in prices, and so far as they are exclusively for Premiums, the Publishers' contracts hold good during the continuance of the present Premium List. The Premiums range all the way from small articles for sending single new subscriptions, up to \$150 articles, and every person can secure some one or more of them now. We believe the present number of this Journal, if shown to non-subscribers as an earnest of what the Volume for 1880 is to be, will prove attractive enough to secure their subscriptions, and every one who takes a little trouble to present the paper to others, and invite such subscriptions, will be entitled to the premiums offered.

**The Sliding Gate.**—"M. J. S.," Butler Co., Pa. On reference to the *American Agriculturist*, for Dec., 1879, page 521, it will be seen that the so-called "Lee patent," on the common sliding gate, and another known as the "Teal patent," have been brought into court in Michigan and defeated, the court having decided that these patents were illegal. This is a sufficient answer to give to any person claiming a patent right fee for the use of any such gate. Thousands of dollars have been fraudulently collected under these illegal patent claims.

**The President's Message** in what it says of the financial position of the nation, its peaceful relations at home and abroad, our abundant harvest, and all other things relating to our material prosperity, will meet with a hearty response from every thoughtful person. But the President says other things, with which we cannot agree, and makes recommendations which ought not to be adopted. In spite of the deplorable figure our Government makes, so far as it has gone into the business of agriculture, he proposes to extend it, and to add divisions of Forestry, and of Veterinary Matters, to the present Department of Agriculture. Even Presidents do not appear well, when they talk on subjects about which they know little, and we regret that a message which begins so well, should have so lame an ending.

**Disease in Fowls.**—"J." When the head and eyes of fowls swell, and fetid matter comes from the nostrils, the disease is Roup. It may be cured by washing the head, mouth, and nostrils, with warm vinegar, and dressing the nostrils and throat with a soft feather dipped in a solution of one dram of Sulphate of Copper (Blue Vitriol) dissolved in a tea-cup full of water.

**Books on Orchard and Gardening.**—We are often asked by those who would select some book as a guide in the different departments of horticulture, which one of several will best answer their purpose. Perhaps we can aid to a selection by enumerating the leading works in each branch of horticulture. For the Orchard, from starting trees in the nursery, planting and general management, no other work is so full and complete as the "Fruit Garden," by P. Barry. It is unfortunate that the title does not convey an idea of its full scope. It describes select lists of fruits of each kind. For a list and descriptions of nearly all known varieties, Downing's "Fruits and Fruit Trees of America" is best for reference. In Small Fruits, "The Small Fruit Culturist and Grape Culturist" by Fuller, and Roe's "Manual of Small Fruit Culture." For Market Gardening, "Gar-

dening for Profit," by Peter Henderson; "Money in the Garden," by P. T. Quinn; "Farm Gardening and Seed Raising," by F. Brill, is a most useful work, and the only one of its kind. For the Flower Garden, "Breck's New Book of Flowers" is still the favorite with those who follow old-fashioned gardening. "Practical Floriculture," by Peter Henderson, is suited to both the professional florist and the amateur—and "Gardening for Pleasure" by the same author is intended for those who wish one book to tell them all that they wish to know on fruits, vegetables, and flowers. There are many other works, which will be found in the advertised book list.

**Extermination of Willows.**—"J. P. T.," Rio Grande Co., Col., asks: "How can Willows and their roots be most easily destroyed?"—Our native Willows, as a general thing, grow where they are most needed, along the banks of streams, where they render most valuable service in keeping the banks from being washed. Those which are above ground, mere bushes, have very long, far-reaching roots, and often of much greater diameter than any of the stems. In clearing land it is desirable to leave this natural barrier to the encroachments of the water. But to exterminate them from land which it is desired to clear, is our friend's question. He says that cutting them with the axe is most tedious work, and asks if any implement is made for the purpose. There are bill-hooks, an old-fashioned implement for clearing undergrowth; the brush scythe, a short, thick, and heavy scythe, made for the work indicated by its name; then there are implements made especially for tropical countries, the "machete" and cane-knives, very heavy, long-bladed knives that are most effective in the hands of those accustomed to them. Among these no doubt something can be found that will make more rapid work than the axe, which will still be required for the larger Willows. A grub-hoe should be used for the roots, and when all of these that is practicable are removed, there will be a continuous sprouting from what remains in the soil; these may be kept down by goats, or perhaps by sheep.

**Atavism, what is it?**—"A Reader." When an animal possesses any peculiarities not found in its parents, as of form, color, disposition, etc., but common to grandparents some generations back, it is said to have obtained them by atavism. It is the cause of croppings out of characteristics in distant descendants; or to put it in another way, a reversion to an older form.

**Fastest Time—An Interesting Table.**

Year.	Horse.	Time.	Year.	Horse.	Time.
1810.	Boston Horse.	2.48	1867.	Dexter	2.17
1833.	Confidence	2.36	1871.	Goldsmith Maid.	2.17
1834.	Edwin Forest.	2.31	1872.	"	2.16
1845.	Lady Suffolk.	2.24	1876.	"	2.15
1849.	Pellham	2.28	1874.	"	2.14
1853.	Highland Maid.	2.27	1878.	Rarus	2.13
1859.	Flora Temple.	2.19	1879.	St. Julian	2.12

**Eating Shot.**—The London *Lancet* cautions those who eat game, to be careful and not swallow the shot by which the animal was killed, as serious results have followed taking Lead into the system in this manner.

**A Horse in Poor Condition.**—"C. T.," Kent, Iowa. A horse that is in poor condition, and troubled with worms, will probably be relieved by a dose of one pint of Linseed Oil, given every third day, for three times, then give weekly a pint of the Oil, with one ounce of Spirits of Turpentine. Feed bran mash, boiled oats and potatoes, giving them slightly warm.

**Jack Rabbits.**—"O. B. O." writes that four years ago parties in Kern Co., Cal., imported greyhounds from England, for the protection of their crops, there being "millions" of the pests in that and adjoining counties. The statement would have been more complete, had he told us what success attended the experiment.

**To Utilize Straw Without Stock.**—"L. P. F." Charles City, Iowa. When stock are not kept by which straw can be made into manure, it is well in many cases to spread the straw over the fields and let it rot, or plow it in—preferably the latter, for if left loose upon the surface it would probably blow into heaps.

**Cotton Seed and Linseed Cake.**—Dr. Lawes estimates the manurial value of these two concentrated foods, at \$29 per ton for the former, and \$33 for the latter. This is more than the market price of cottonseed meal with us at the present time. Does this not appeal to the American stock feeder, to use these concentrated foods more abundantly!

**Bran as a Food** has not been fully appreciated. The laxative tendency does not produce any unsatisfactory results, provided the bran is fed as it should be. A slight laxative condition of the bowels is better than the constipation that a lack of such food produces. Besides, the bran is rich in phosphates, so essential to the development of healthy stock.

## The American Agricultural Association.

Last month we announced that the preliminary steps had been taken towards the formation of an Agricultural Society which should be truly national in its scope and membership. The meeting for final organization was held in New York December 10th-12th and was quite as largely attended as the most sanguine friends of the enterprise could have expected, while the assemblage was of a character such as one rarely sees brought together. Indeed, the gathering was a remarkable one for the solidity and dignity of its members, it being composed, with few exceptions, of men of middle age. The first day was devoted to preparatory work, and in the evening the meeting was addressed by Prof. A. R. LeDoux upon the "Adulteration of Seeds," and by Dr. M. Miles on "The Correlation of Forms in Animals," abundantly illustrated by the aid of one of McAllister's fine stereopticons. On the second day the election of officers took place, which resulted as follows: *President*, John Merriam, of Maryland.—*Vice Presidents at large*, N. S. Townsend, Ohio; Moses Humphrey, New Hampshire; J. C. Stevens, Ohio; J. B. Bardwell, Maine; G. Gregory Smith, Vermont; David Taggart, Pennsylvania; E. H. Hyde, Connecticut; John Scott, Iowa; George H. Cook, New Jersey; Ashbel Smith, Texas; C. V. Riley, District of Columbia.—*Vice Presidents*, L. L. Polk, North Carolina; Dr. Henry M. Ridgley, Delaware; C. W. Thompson, Minnesota; S. D. Gillett, Illinois; Daniel Needham, Massachusetts; Edward D. Pearce, Rhode Island; J. W. Avery, Georgia; Ezra Whitman, Maryland; John D. Adams, Arkansas; D. Wyatt Aiken, South Carolina; Governor George F. Drew, Florida; F. T. Francis, Alabama; Governor Alcorn, Mississippi; Colonel J. B. Killebrew, Tennessee; Cassius M. Clay, Kentucky; J. Floyd King, Louisiana; Roger W. Woodbury, Colorado; John Bidwell, California; S. G. Reed, Oregon; John P. Jones, Nevada; Henry G. Davis, West Virginia; General Gilbert S. Meem, Virginia; Claude Mathews, Indiana; Chester Hazen, Wisconsin; H. G. Wells, Michigan; J. H. Scofield, Kansas; D. H. Wheeler, Nebraska; Prof. G. C. Swallow, Mo., and Lawson Valentine, New York.—*Directors for one year*, N. F. Sprague, Vermont; P. M. Pulford, Maryland; Thomas M. Holt, North Carolina; T. E. Gould, Illinois, and J. N. Coleman, Missouri.—*Directors for two years*, Major Alvord, Massachusetts; A. L. Kennedy, Pennsylvania; J. T. Henderson, Georgia; McGrath, Kentucky; Trumphy, Michigan; J. B. Grinnell, Iowa; Powell Clayton, Arkansas.—*Directors for three years*, Governor Fred Smyth, New Hampshire; General N. W. Curtis, New York; Robert Beverly, Virginia; M. J. Lawson, Ohio; William S. King, Minnesota; Henry Hubbard, Colorado; General A. T. A. Torbert, Delaware. Mr. J. H. Reall was chosen *General Secretary*, and Lawson Valentine, of N. Y., *Treasurer*. The Board of Directors appointed an Executive Committee, to consist of: The Senior Vice-President, N. S. Townsend of O., and others.

The principal addresses on the second day, were by Professor C. V. Riley, of Washington, on Agricultural Advancement in the United States, and by Prof. W. O. Atwater, of Wesleyan University, Middletown, Ct. Both gentlemen took occasion to compare our government's efforts on behalf of agriculture, as manifested in the seed-shop at Washington, with the unostentatious, inexpensive, but wonderfully efficient methods of European governments. On the third and last day the Society was addressed by Prof. X. A. Willard on The Dairy; Prof. W. H. Brewer, of Yale, on Science and Agriculture; Peter Collyer, Chemist to the Department of Agriculture, Washington, on Sugar from Sorghum and Corn Stalks. The concluding address was by the Hon. J. B. Grinnell, of Iowa, who gave a very enthusiastic and patriotic address on agriculture in general. We look upon the beginning of this Society as a success, and as full of promise. An excellent spirit pervaded the meetings, which we trust may be found in all future sessions of the Society.

**The American Dairymen's Association** will hold its 15th Annual Convention at Syracuse, N. Y., January 13-15. An attractive programme is sent us, containing the subjects of addresses by Prof. James Law, E. W. Stewart, G. C. Caldwell, L. B. Arnold, and others. All Dairymen are earnestly invited to be present and participate in the work of the Convention.

**Manure a Product of Feeding.**—We wish to call the attention of all readers to the above point, as set forth in Professor Atwater's article. Read it carefully.

**Hatching Codfish.**—Professor Baird's attempts in hatching codfish have been successful, and the Commissioner hopes to re-stock the waters of New England—waters where formerly this valuable fish was abundant.

**Pine Cones for Kindlings.**—When dry, the cones from pine trees are excellent for starting fires; they so abound in resin that a small amount answers.

## Agricultural Stations and Departments.

In an address before the "American Agricultural Association," on Dec. 12th last, Prof. W. O. Atwater gave an account of the European Agricultural Experiment Stations, and then contrasted our so-called Department of Agriculture with these useful institutions. Among other things he said:—"In 1876, the annual expenses of the *Sixty Six* German Experiment Stations was \$156,750. Fifty-two per cent of this came from Governments, 17% from societies and public-spirited individuals, and 31% from fees for analyses. According to the report of our Commissioner of Agriculture for 1878, the running expenses of our Agricultural Department from 1839 to 1878, forty years (exclusive of double this sum for cost of printing and buildings), were over \$85,000 per year; total, \$3,404,754.13. The current expenses of the last three years are: 1877, \$174,686.96; 1878, \$188,640.00; 1879, \$204,900.00. The current expenses for 1878 included for salaries, \$65,640.00; for collecting statistics, \$15,000.00; for laboratory, \$1,000.00; for purchase and distribution of seeds, \$75,000.00. Roughly speaking, we may say that the system of accurate experimenting in agricultural science, whose results we have been considering, dates from about the same time as our Agricultural Department, although the Experiment Stations commenced a dozen years later. No exact figures of the whole expenses of the European Experiment Stations are attainable. It is safe to say, however, that they have cost the Governments very much less than our Department of Agriculture has cost us—i. e., less than the current expenses of the Department. The printing of the Reports costs as much or more than the current expenses. That is to say, either item, Current Expenses or printing of Reports, has cost the U. S. Government more than the European Experiment Stations have cost their Governments. The best information—nearly all the definite, accurate information we have of Agricultural Science has come from this European work. How much has come from the U. S. Department, everybody knows. "Look on this picture and then on that."

The Prussian Government pays for its thirty Experiment Stations which include the most productive ones in all Europe, almost exactly the same sum per annum that the U. S. Agricultural Department has almost uselessly expended for the purchase and distribution of seeds.

## The Second International Dairy Fair.

In January last, we gave an illustrated account of the Dairy Fair held in Dec., 1878. Though this was an impromptu affair, its success was such that an Association was formed, which is now, Dec., 1879, holding a second exhibition. As we go to press, the Fair is in its fourth day, and yet all the details are not complete, much of the machinery is not in working order, and as the judges have not made their awards, the names of competitors are not placed upon their exhibits. The boy who boasted that he knew how butter was made, said: "You take a long kind of pail, and swish a stick up and down in it. Then you want a cow." We will, as a "condition precedent," put the cow first, and say that the exhibition of dairy stock is very much larger than at the former exhibition. The greater share of the animals are placed in the "Machinery Annex," and we think it a mistake not to have had all in the same place, as one can better compare the animals when close together, and the confined air of the main room, where the butter and cheese are to be judged, would have been free from that animal odor which cows, however choice and however well cared for, will give off. To begin with the cow. The largest number is exhibited by William Crozier, of Northport, L. I., who has in all 37 head, in which the Jerseys predominate; but there are also Ayrshires, and Gurnseys, including besides cows, bulls and heifers, and all the way down to the four-weeks calf. Some of the animals have a remarkable record. One of the bulls seems to us a perfect specimen of the Jersey breed. James Nielson, New Brunswick, N. J., exhibits about a dozen Dutch cattle, which he has labeled "Holsteins," although no such breed is known in Holland; his pens include a very fine bull, with the appropriate name "Taurus." Dr. A. D. Newell, of the same place, has some fine Jerseys, and so has John J. Holley, of Plainfield, N. J. S. M. D. Wells, Wethersfield, Conn., sends representatives of his noted herd of Ayrshires; Harry A. Weed, Stanford, Conn., and his neighbor W. H. Walmsley, both show fine Devons for which they claim excellent milking qualities, and that they will turn off as excellent beef animals; F. W. Decker, of Dutchess Co., N. Y., has Shorthorns, two of the cows being white.

In Cheese, Messrs. H. K. & F. B. Thurber & Co., whose pyramid we noticed last year, confront the visitor as he enters, with an obelisk of this edible, 40 feet in height, built up of cheeses of various kinds, and embellished by quaint mottoes. The next most conspicuous object is the pyramid of bags of salt erected by F. D. Moulton &

Co., of which it is not necessary to say more than it is "Ashton's Factory Filled." W. W. Ingraham, of Jefferson Co., Wis., has a handsomely arranged pyramid of red and white cheeses. A very attractive exhibit is one of imitations of the various European styles of cheeses by Roethlisberger & Gerber, New York; here are cheeses in all possible sizes, shapes, and colors. We notice that the Limburger is placed under glass, a rather frail inclosure for so strong a subject. Butter thus far is labeled by States, but the names of the makers will be given when the awards have been announced. Dairy appliances, in the way of churns, to the very last step in packing and marketing, are numerous almost to bewilderment. It is interesting to note the great variety of devices for accomplishing the same end: the simple act of setting cream is made the subject of several inventions, while churns are proverbially endless in styles. It would occupy pages to give even brief mention of these "appliances." The machine for separating cream by centrifugal force, was not yet ready for operation at the time of our visit; much is expected from this application of centrifugal force in the creamery, and it is thought by many that it will effect a revolution in butter-making in a double sense. Whitman, Burrell & Co., Little Falls, N. Y., have a cheese factory in full operation; it forms a most attractive feature of the fair to city visitors, who naturally have a curiosity to see how so generally an article of food is prepared.

## Sundry Humbugs.

As the present number of the *American Agriculturist* will be read by many thousands we have never before addressed, we would say a word to them. The exposure of frauds, especially those upon farmers and rural residents, has been for many years a regular department of the *American Agriculturist*. It was nothing of our own seeking, but grew up spontaneously from the necessities of the case. By far the larger share of the schemes intended to defraud country people, have their origin in cities, especially the City of New York, and it was very natural, when these were presented to the rural readers of this paper, that they should appeal of us, as we were in most cases the only persons in the city of whom they could inquire as to the proposed schemes. From small beginnings our correspondence relating to humbugs has grown up to be something formidable; the amount of labor it entails is only compensated for by the abundant assurance, which comes to us from all quarters, of the great utility of our exposures.

### WHAT IS A HUMBUG?

We use the word "Humbug" as a convenient term for every scheme to obtain money or its equivalent without making a fair and proper return, as well as for every other form of imposition and cheating. A very comprehensive term it is, as the devices it includes are well nigh innumerable, and as the ingenuity of rascality is by no means exhausted, new forms of humbugs are constantly demanding our attention. While those who have long been readers of the *American Agriculturist* understand the matter, it may be well for us to say to new friends that this column is conducted solely with a view to

### THE GOOD OF THE COMMUNITY.

It can not be made a medium for the settling of private grievances, and it will be of no use to send us a request to "show-up so-and-so as a humbug" unless accompanied by full evidence that the party accused is worthy of a place in such select company. There is perhaps no other subject upon which we receive so many letters as

### SPECULATIONS IN STOCKS.

We had said all that was needed upon this matter, but many new readers have recently joined our circle, and frequent letters come from those who have not seen what has been stated. The country must be flooded with the circulars of parties who are, or who call themselves, "stock brokers." These present the case in a most persuasive manner; they show how a small sum may become large, and a large one larger, by handing it over to the senders of the documents. Our letters of inquiry almost invariably ask as to the character of the parties sending the circulars, asking if they will "do as they agree to do." It is impossible to give a "confidential answer" to any letter of inquiry, and we must here

### REPLY TO MANY LETTERS

by saying that we have no little personal knowledge of any of the senders of the circulars, we have no reason to doubt that most will "do as they agree to do."

—Let any one not infatuated by the idea of making money rapidly, read these circulars, and see how little they "agree to do," except to take the money sent and speculate with it. The character and business responsibility of the parties are not in question with us in our objections to

### THESE STOCK SPECULATIONS.

We advise our readers to avoid them, not because of the parties who carry on the business, but because of the character of the business itself. The fact that many bar-keepers are totally abstinent men does not prevent opposition to liquor-selling. The opinion of the best business men, bankers, and merchants of all kinds, is, that the kind of stock speculation proposed in the circulars referred to is pernicious in its influence, that its effects upon those who practice it are similar to those of gambling, and that in the interest of

### SOUND BUSINESS PRINCIPLES

it should be discountenanced and suppressed. Regarding success in such speculations as only more unfortunate than losses, on account of the infatuation it encourages, we have uniformly discouraged our readers from engaging in any of the schemes, no matter how attractively they may be presented, or how great the prospect (or hope) they present of sudden gain.

### LOTTERY SCHEMES IN CONGRESS.

The consternation among lottery men, caused by the enforcement of existing laws has been already mentioned. The Post-master General has in the second week of its session caused to be presented to this Congress an amendment to the law as it now stands, which covers the defects of that law, and facilitates the exclusion of lottery matters from the mails. The lottery people are to make an appeal to Congress, and present their grievances; watch the votes when the bills come up, recollecting that the lottery chaps have money in plenty, and it is a question to them of life and death. Watch the votes! But if lotteries are to be excluded, why not the stock speculators, which offer the lottery, only in another form? Do not make fish of one and flesh of another. . . . J. G. B., St. Louis, Mo., sends us a remarkable circular of a

### "PASTOR-I-AL COLLEGE."

Now this is not, as some may suppose, anything like a theological school where pastors are educated—no—this "Pastor-I-al College" guarantees "in a course of thirteen weeks, to teach any man of ordinary ability the business of raising cattle and horses, sheep," etc., etc. Now here's a college as is a college. It underscores the important assertion—"We do not teach from books"—probably not, and with good reason. It looks very much as if the aim and object of this circular was to sell a work for 75 cents. . . . Last month we gave the manner in which

### ROGUES WELCOME STRANGERS.

There are gangs of rascals who hang about the streets leading to the principal depots, ferries, etc., to overhail strangers, and they actually watch for their prey upon Broadway in broad day light. Their method is to pretend to know the stranger, be glad to see him, get at once into his confidence, and on one pretence or another, such as showing samples, etc., get him into some place where they can fleece him. Incredible as it may seem, this game is frequently successful. Soon after giving an account of this matter last month, a case was reported in the daily papers, in which a clergyman from Illinois fell into the hands of these chaps. One who pretended to know him induced him to go into a place to see some samples of tea. Here were several friends of the tea-man. One of these complained that he had lost a sum of money at cards, the others laughed at him, the minister "reasoned" with him, remarking that "he did not see how he could be so foolish."—"But did you ever see the game played?" said Scamp.—"Never," said Parson.—"Well, I should just like to show you how it was done. Have you any money?"—"Yes, 40 or 50 dollars," said Parson.—Such was his anxiety to understand the matter that he

### ACTUALLY PUT DOWN HIS MONEY

for two of the rogues to show how the game was played. They played, and in a short time one of the rogues won all the parson's money and put it in his pocket. Of course, that was the last of that money. There was a row, arrests were made. Parson could not give bail for his appearance at the trial, and was locked up in the House of Detention—which is the next thing to a jail—with a prospect of remaining there until the trial, some two months off. Moral:

### AVOID ALL ADVANCES OF STRANGERS,

if you are a stranger yourself in a strange city, especially in New York. . . . The "Chicago Tribune" has been showing up the operations of a chap with a

### "MAGIC BONE DISSOLVENT"

not a dissolvent for converting dead bones into superphosphate, but for curing spavin, curb, ring-bone, "within thirty-six hours, without breaking the skin." Quackery in horse medicine, is not so rare a thing, but we were attracted by the name "Horton." Could it be our Hor-

tion, he of the wonderful "Stump Extracting Powder." To be sure, the Chicago Horton was a "C. G.," while our Horton was a "W. V.," but the difficulty of finding any Horton, the presence of some one else to answer questions in both cases, lead to the fearful suspicion, that one who was on so familiar terms with lightning, as to cause it to come up a wire with "a pinch of salt on its tail," and annihilate a veteran stump, would be able to convert a "W. V." into a "C. G." ... In Chicago, where the great interest is grain, and they make "corners in corn," they play their little games of

#### PLOTS AND CALLS IN WHEAT

after the manner that is done on stocks in New York, and the business there, as in New York, is done by parties who find their customers at a distance from the city, and among the rural population, or "grangers," which is the slang name of the city papers for farmers.

#### THE BIBLE AND DICTIONARY OFFERS,

notwithstanding that it was long ago exposed, is still carried on by parties near New York, though the originators of this scheme, in small places, have been stopped long ago. The plan is to advertise a dictionary worth \$5 or \$6, for 35, or 54 cents. In the cases that have come to our knowledge, the book sent has not been worth in the trade, as much as 25c. wholesale. If, in cases like this, people would recollect, that really valuable things are never sold for less than they are really worth, such games could not last. When the parties who advertise these \$6.00 Dictionaries for 35 cents, actually send the book they really advertise, one gets near his money's worth; the fraud is in representing the book as a Six-Dollar one.—A "wounded bird" in Brooklyn, who applied to himself our hit at this misrepresentation in May last, tries very hard to strike back by sending on his postal card a statement that his "little book" is worth so much more than the publications of O. J. & Co. Keep on doing so, Mr. Blank, if it does you any good. We never object to such free advertising ... When an article is offered for *much less* than its real value, it is safe to conclude, that its value

#### IS NOT AS REPRESENTED,

or that there is some object in making the offer which is not apparent. It is safe to let alone all articles, that, like these dictionaries, are offered at less than a tenth their alleged worth.... A chap in Philadelphia, offers a "New Domestic Bible." He describes a large Bible, the contents, number of engravings, size of pages, and all that, and claims it to be "as good as those sold for \$15 in any book store," and says: "To introduce our Bibles, we agree, upon the receipt of \$1, to pay the postage and other expenses, to send a copy of the Holy Bible" etc. "This is too thin.... We have already had batteries of many sorts, but never before have we had the

#### "MINIATURE BATTERY."

A long circular in very fine print, tells all about it. The pictures are only three, but telling. One is a man, or the upper part of him, heavy as to beard, and nothing as to clothes, with one of these batteries right over his breast-bone, and he don't seem to mind it a bit. The second is a picture of the earth; that respectable old planet is being badly struck by just the crookedest kind of lightning. The third is a picture of the Battery, "of the exact size," which is that of half a dollar. The "Professor" who has this miniature Battery, is down upon all Electric Chains, Belts, and Bands—and we should think he would be—for they give down only common, plain electricity, old-fashioned lightning as it were, but this Battery is up to the times with a new sort, the

#### REAL GIMLET-POINTED LIGHTNING!

This, absurd as it may seem, is an actual claim; we are told that the Professor said: "That the various blocks of metal were so placed, that when the electricity was formed, it would be *formed in gimlet shape*, and he said it would enter the system in that form, and *pass on twisting*, until it spent its force." Yes, the lightning is not only "gimlet pointed," but it goes on a "twistin'." On the whole, we prefer the old style. Yet people will read nonsense like this, and believe it. Boyd, you are the worst electrical humbug yet. ... In medical matters, the

#### RECIPE NUISANCE

seems to be the most prominent. We would say to our newer readers; if tempted by the advertisement of any young fellow, whose "sands of life are fast running out," or any "retired missionary," or any chap who met a missionary in foreign lands, or of any one else, to send for his or her recipe,

#### DON'T!

This recipe business is one of the meanest forms of quackery. The chaps offer a Recipe. It will be entirely in unmeaning jargon, or all the articles but one or two will be well known things, but these, the most important will be names, unknown to medical, or any other science. The chaps inform the person to whom the recipe is sent, that said articles are very difficult to obtain, that druggists never have them fresh, (nor at all, as their "ain't no sich") and that they, at great trouble and expense, have im-

ported a lot of the "Original Jacobs," which they will put up for the sufferer, at what will barely cover the cost—\$3 or \$5.—We would say a word to our new friends,

#### ABOUT ADVERTISING DOCTORS,

which may save them some trouble in writing to ask our opinion of this or that one. We regard every doctor who advertises that he can cure this or that, especially those who warrant a cure, as an enemy to the public welfare, and to be avoided. We do not know any of them, and advise every one to keep clear of all of them. Moreover, every medical compound, the composition of which is kept secret, we regard as dangerous to the public welfare, and instead of being taken by the people should be taken by the police and destroyed; as our laws are not up to our needs in this respect, we can only advise every reader of the *American Agriculturist*, to let everything of the kind entirely alone.

#### LATER—ABOUT STOCK GAMBLING.

We have alluded above to the general excitement on the subject of stock speculations, as indicated by the numerous letters to us. It seems to be an all-pervading mania, and it is said that even women participate in this form of gambling. A recent paper states that one lady's operations were far from encouraging. She gave her broker \$1,000 with which to operate; her investment brought her nothing, but the broker brought in a bill for \$5,000 for his commissions. This looks like a large story, but it appears in a commercial paper of good standing. A friend who knows about such matters informs us that the extent to which the country people are engaged in these speculations is astounding; they are known in

#### THE SLANG OF THE STREET AS "THE LAMBES,"

and the knowing ones talk of "shearing" their country customers. A farmer of our acquaintance has called in to request us to present our warning with still greater force. He says that a neighboring farmer, who, in spite of his warnings, has engaged in the "put and call" business, has just been sold out under a chattel mortgage made to those from whom he borrowed money to speculate with, in the vain hope of getting back that which had gone before. It is the same old, old story; when one once becomes infatuated with the desire to get rich suddenly, by some lucky chance, whether in the lottery, or by stock gambling, he is already on the high road to ruin. To those who have become engaged, ever so little, we say, stop short. To those who are hesitating on the edge, we say: Touch not! The motto appropriate to all the avenues to Wall street is:

"Let him who enters here leave Hope behind."

**Shape of Meat-Producing Animals.**—The best animals for producing meat are those with large and healthy organs of nutrition, and sufficient room near by for the storing away of the meat. These two and other reasons determine that the best meat-producing animals are built on the plan of a square when viewed from before or behind, and a parallelogram in side view—or what is called the "rectangular type."

**Self-Sharpening Horse Shoes.**—By the simple expedient of rolling a steel plate in the center of the iron from which the shoe is made, the calks of the shoe have a hard steel center, and as the soft iron wears away by use, the sharp steel is left to prevent slipping. The manufacturers, Messrs. Shoenberger & Co., of Pittsburgh, Pa., send us a part of a shoe that was worn all winter, which shows the effect of wear in exposing the steel center. Those who travel upon icy and frozen roads know the difficulty of keeping the horses properly "sharp," especially if they live at a distance from a blacksmith; with a set of these shoes, the animal is prepared for all weathers, and can travel and work more effectively than when in danger of slipping, and with greater safety to the driver. The firm make self-sharpening shoes of the ordinary form, and also the "Snow-shoe Pattern" in which the shape is such that the snow can not ball upon the animal's feet.

**Ensilage: Silo Opening.**—The first Silo in America, built on the French plan, of M. A. Goffart, was opened at "Winning Farm," J. W. Bailey, proprietor, Billerica, Mass., on Dec. 3, last. This Silo, or fodder pit, is 40 feet long, 12 feet wide, and 16 feet deep, roofed, and having a capacity of 500 tons. It was partly filled with green corn stalks, cut by an ensilage cutter, the pieces being 4½ inches in length. After this cut fodder had been thoroughly tramped down by men, a layer of straw, 12 inches thick, was spread over it all, and the whole covered closely with planks, upon which about 50 tons of stones were placed. This was done early in October. At the opening of the silo, the fodder was found to be in an excellent state of preservation; at first a little sour, but in a short time this sourness passed away, and when fed to cattle or sheep was eaten with a relish. A number of agriculturists and members of the press were present, in fact, the "opening" of the silo was well attended, and voted a success.—Mr. Bailey is so well pleased

with his experiment that he will practice this method of preserving green fodder in a green state to a larger extent the coming season. Others have also expressed their intention to erect silos at an early date. This is one of the most important of recent improvements in agriculture, and one which every one who raises corn fodder should investigate before the next crop is harvested.

**A Safe and Handy Knot.**—It frequently happens that a rope, strap, or even string, breaks, and it is necessary that the parts separated should be securely fastened together. One of the best methods of tying a

Fig. 1.—TYING THE KNOT.

firm knot consists of forming a loop of one broken end, after which the other portion of the rope is passed through it, as shown in figure 1. If the rope or strap is long, the same knot may be tied by passing the broken

Fig. 2.—PARTLY DRAWN UP.

end under, and then around the loop, and under itself, thus saving the trouble of drawing the whole length of the rope through the loop, a back-handed way of arriving

Fig. 3.—THE COMPLETE KNOT.

at the same result. This knot when tied, and still loose, is as shown in figure 2; when drawn up tight, it is as in figure 3. This knot is especially adapted for tying pieces of harness, halters, etc.

**Twin Lady Apples.**—Our notice of twin apples last month, reminded Mr. W. W. Young, Jefferson Co., Ky., that his Lady Apple trees frequently bore twin fruit, and sends us three specimens of this doubling. He thinks the variety given to producing such freaks, as he frequently finds them in picking the fruit. We quite agree with him when he says, "We consider it about Christmas a very fine apple."

**Hardened Glass,** from which great things were expected, has been but little mentioned of late. Recently, in view of the great losses by hail in England, it is proposed to use the Bastie, or hardened glass, in green-houses and for other horticultural buildings.

**Hard-Pan—What is It?**—"M. E. C." Soils are divided into three classes: *Surface Soil*, *Subsoil*, and *Hard-pan*. The surface soil is the upper portion and that which is turned by the plow; in fact, the soil that interests the farmer most. The subsoil is below the surface soil, more compact and often of a different color. Sometimes the line between the surface and subsoil is quite distinct, but generally not. Hard-pan is a still harder layer than the subsoil, and lying below it. This hard stratum may be but a short distance below the surface, while in other places it is not to be found. It is a very hard soil, or one that is approaching the nature and texture of a rock.

**Michigan State Farmers' Institutes.**—The State Board of Agriculture has decided upon the times and places for holding a series of Farmers' Institutes for 1880. There will be six such gatherings for lectures and discussions, held at widely separated points in the State, during the month of January. The Professors of the Agricultural College will take a prominent part in the meetings, two or more of them are to be present and give addresses at each Institute.

**Largest Yield of Wheat.**—The Territorial Fair Association of Montana has awarded the first premium for the best acre of wheat, the yield being 102 bushels. This is believed to be the largest known yield of wheat.

**Hired Help in Winter.**—The average farmer—that is, one with 150 acres devoted to mixed husbandry—if he has no large boys, can generally find employment for one hired hand through the winter. There are many things that he can do as well as in summer, if not better, as the getting out of timber, rails, the year's fire-wood, and doing much shop-work, if he is handy with tools. In this way a man can be kept the year round and constantly on hand with very little more expense and much more comfort than to hire a new hand each spring.

**American and English Agriculture** as seen by English eyes. The average yield of wheat in Great Britain is 28 bushels per acre. Estimating rent, interest on capital, outlay for manure and labor, and the crop costs £8 per acre. "The Western farmer who has £2 sterling invested in his soil and its equipments, his expenses per acre would be somewhat as follows." Interest on capital, 4s.; plowing, 10s.; seed, 6s.; reaping and binding, 10s.; threshing and marketing, 2s.; total, £1, 12s. The fourteen bushels (which is the average) of wheat will give a return of 42s., or a profit of 10s. per acre. "Two years' profit thus moderately estimated would purchase the fee-simple of much of the land in the Western States." The American farmer under the circumstances has much the larger margin of profit. "The American of a certain type has an instinctive aversion to the pursuit of an unprofitable calling; he has a wonderful capacity for accommodating himself to circumstances. If wheat-growing does not pay he tries dairying or gardening, and failing that, will cut down lumber or split rails, keep a store or 'run a hotel,' or even make politics his profession." The English writer claims no such smartness and versatility for his farmers, and does not expect it, as they are "not to the manner born."

**Pleuro-Pneumonia.**—From the English agricultural papers we learn that this dreaded and destructive contagious disease is breaking out in various parts of Great Britain. One grazier in Surrey has lost 44 head, and the authorities have ordered the immediate slaughter of the rest of the herd. One farmer in North Staffordshire was fined £10 for removing the remainder of his cattle to an adjoining farm. "Strong measures are being adopted to stop the infection."

**Variety of Food.**—It is a well established fact, that a single kind of food is not enough for the best growth, health, and comfort of animals. Like ourselves, the stock which we keep, *does* relish a change of diet—thrives better with a change of pasture so to speak—and gives fuller returns for the trouble of providing the variety of foods. Coarse fodder should be mixed with that which is of a finer nature; and the highly nitrogenous, fed with substances weak in nitrogen. Some farmers will feed their sheep corn one morning, and barley or oats the next, and thus keep up a continual surprise, lightened by a lick of salt now and then. It is the same love of change, which makes the colt, cow, and even the oldest horse feel glad when turned into a new field.

**Treatment of Frozen Plants.**—In times of the severe cold, the more tender plants in the window will sometimes be chilled and frozen. Such plants should not be put near the stove, to be thawed out; but kept where the temperature is a trifle above the freezing point that the thawing may be gradual, and in the dark, that deleterious chemical changes may not take place. If severely touched with the frost, it is best to remove the frozen parts, that new stems may be forced out from the buds below. Water freely, and finally bring them to the ordinary temperature for house-plants; 65 to 70 degrees.

**Read the Market Columns.**—The reports of Commercial Matters are made by experienced men, and with great care. These columns furnish much valuable information in the amount of various agricultural products, that have been bought and sold in the New York Market, and the comparisons with those of last year, are instructive. For example, under "Current Wholesale Prices," observe the advance in Potatoes, Timothy seed, Quinces, and especially in Apples. It will pay for all who have produce to sell, or to buy, to read the markets.

**Wood Ashes.**—The value of ashes as a fertilizer, depends principally upon the Potash and Phosphoric Acid they contain. The percentage of these varies largely, in ashes from different woods, varying from 10 per cent to 24 per cent for the former, and 4 per cent to 12 per cent for the latter. This would give not far from four to five pounds of potash to a bushel of ordinary mixed unleached ashes, which, reckoned at 4½ cents per pound—the present market value of potash in the commercial fertilizers—would give the value of a bushel as from 18, to 22½ cents. With due allowance for the Phosphoric Acid and the Lime—the latter making up the largest part of the ashes—it may be seen that a bushel of unleached ashes, is worth from 25 to 30 cents at the present time. Ashes, to secure the best results, should be thoroughly mingled

with the soil. In this way, the best physical, as well as chemical effects are obtained. It is self evident that crops requiring larger amounts of Potash, will be the most benefited by the application of ashes, as the root crops, cabbage, tobacco, etc. Forty to fifty bushels per acre, is a good application.

**An Extensive Country.**—Not many days ago a prominent English agriculturist called at our office on his way home from a two months' run through some of our Western and North-western States. The feeling that was uppermost in his mind was the bigness of our country, and the large scale upon which everything is done by the American farmers. To use a familiar expression, he thought there were "millions in it," in rich acres, in bushels of grain, in heads of cattle, and in dollars for those who are at the work. Uncle Sam has in that snug little farm of his over four hundred million acres of land.

**Root Pulp and Cut Straw.**—As a matter of experience, it is found that the mixture of cut straw and root pulp, alternate layers of each, should stand for at least 24 hours before being fed, after which it becomes heated of itself, and the cattle eat it with great relish. There is nothing better for young and growing stock.

**The Illinois Fat Stock Show.**—The second annual exhibition of Fat Stock, held in the Exposition Building, in Chicago, was all that a large collection of the finest animals—horses, cattle, sheep, and swine, could make it. "Taken as a whole, in point of entries, in excellence and variety of the various classes, in the perfection of fattening, and in the attendance from day to day, this second annual exhibition may be called a most pronounced success, and will, it is hoped, be continued from year to year, until it really becomes what, in the outset, was intended to make it—the great National Show of the Fat Stock of America." During the show, a large specimen of each breed: Hereford, Shorthorn, and Devon was slaughtered, with the following interesting results:

Part of Animal.	Hereford.	Shorth'm.	Devon.
Gross weight.....	1,963	1,794	1,614
Head, ".....	55	47	49
Hide, ".....	106	90	95
Gut, ".....	113	97	95
Rough, ".....	178	155	145
Fore Quarters, weight...	725	611	552
Hind ".....	592	568	503

It will be seen that the Shorthorn has the greatest proportion of more valuable parts. A series of such comparisons would be of great value to fatteners of stock.

**Parent and Offspring.**—"Which parent has most influence upon the offspring?" This is a question which is coming up every day, and one that is almost impossible to answer. It is now well established that a thorough-bred animal, that is, one bred in the same line or strain of blood, and has thereby had its characteristics fixed, has the greater control over the characteristics of the offspring, be the parent male or female. A Shorthorn bred to a Native will have the Shorthorn points predominant in the offspring. Other things being equal, the vigor of the parent, high constitutional development, or what we are pleased to call *vitality*, is claimed by breeders to have more or less weight in shaping the constitution of the offspring. It is claimed by some that certain functions and organs are determined by the male, while others are under the control of the female. Thus the external character—outward structure—is said to be due to the male, and the inward to the female—as, for example, a cross between a dog (male), and wolf (female), gives more external marks of the dog than when the sexes are reversed, but there is so little definitely known in this regard, that at the present time it can only be said that it is not satisfactorily established how far, and in what directions, each parent controls the offspring.

**Old and Young Stock for Fattening.**—If one but takes the trouble to look over the reliable, recorded experiments of the feeding of pigs, steers, and other stock, it will appear evident that it takes less food to produce the same increase in young, than old stock. Such being the case, beef and pork growers should make it a point to fatten their stock so soon as it is fully grown. The greatly superior quality of the meat, as well as its cheaper production, both encourage the practice.

**Horn Buttons** are now mostly made of the hoofs of cattle, and not of the horns as formerly. Cattle hoofs sell at the present time, for about \$50 per ton. The products of neat stock are very numerous, and there is scarcely a particle of the whole creature that goes to waste.

**Pampas Grass Plumes** have become a regular article of trade with the florists and seedsman, and are among the popular articles for the winter decoration of rooms. The Pampas grass, *Gynerium argenteum*, is a native of South America, and requires winter protection

in the Northern States; it succeeds admirably in the Southern States, and reaches its greatest perfection in California, from which State the greatest supply is derived. C. A. Reed sent a sample a short time ago, showing how finely this grass develops its silvery plumes at Santa Barbara. This grass is dioecious, i. e. has its sexes in different plants; it is the pistillate plant which has the more showy plumes. In the climate of New York it may be preserved by placing a box or cask over it and filling that with leaves, placing on a cover to shed rain; it is worth this slight trouble as a large clump of the foliage is a stately object, even should it fail to flower.

(Basket Items continued on page 33.)

## Bee Notes for January.

At this quiet season, so far as regards the operations of the apiary, it is proper for those who have not introduced the Italians into their hives, as well as those who are about to commence bee-keeping, to consider the claims made for superiority of the Italians over the ordinary, or black bees. In the first place, the Italian bees are much more beautiful than the black, a point not to be overlooked in the choice of anything, even if all the other qualities are equal. They are more prolific; the queens depositing more eggs than the native. The expert bee-keeper can distinguish the Italian eggs by the compactness with which they are stored in the combs. The Italians are more hardy than the natives, venturing out in colder weather, and doing work while common bees remain at home. They, therefore, swarm earlier, an important factor in bee culture—the hives become populous early in the season, thus securing a large working force by the time the flowers are ready for them. As a natural result from what has just been said, the Italians gather more honey than the natives. Again, they work upon plants that the blacks do not visit, which, of course, gives them a wider range for honey gathering. Cases are known where Italians were gathering white honey exclusively, while the common bees were working only on the Buckwheat. The Italians are notably fond of the Red Clover, and will gather much more honey from this plant than the natives, which derive but little from it.

As they are more vigorous than the natives, they are better able to protect themselves, and to defend their stores, being more watchful and swift to discern the enemy. If harshly treated the Italian is worse to handle than the native. This naturally follows from its superior vigor and more active disposition, but when treated kindly, experience has shown them to be more docile, and more pleasant to manage than the others. The honey-comb made by the Italians is more compact, and presents a finer appearance than ordinary comb, the difference being so marked that experts claim that they can tell the kind of bee that produced a given box of honey. Lastly, the Italians are much longer lived than ordinary bees. This has been proved in many cases, and is a strong characteristic in favor of the foreign bee.

## A Test Record for Dairy Cows.

For some time past both the breeders and the purchasers of pure-bred, herd-book-recorded, dairy cows, have been convinced that something more is required to give substantial evidence of value than the bare pedigree of an animal entered in a Herd-Book. A few experts, who know the whole history of the best animals, may have been able to judge of the possible merits of a particular animal by her pedigree, but to the large majority of purchasers, the recorded entries were of no more significance than the hieroglyphics which Texan cattle-men brand upon the flanks of their cows. Mystery is always impressive. And though some people like to be mystified, the larger number of dairymen, who have kept pure-bred animals, have been greatly dissatisfied with the uncertainties of the Herd-Books. Recently some facts in connection with the shipment to the West, and sale there of some cows recorded in the Jersey Cattle Club Register, have opened the eyes of the purchasers of pure-bred cattle, for they have been assured by the best authority that although a cow may have been recorded in the Register, and her pedigree may be perfect, yet she may possibly be "a worthless brute." This shock to the confidence of persons who had a profound respect for "a record," has greatly helped the impression that something more is wanted to give the pedigree a meaning and a value; and that this need is a record of performances of the cows entered in the Herd-Book. It is proposed by some well-known and influential gen-

tleman to establish a system of tests of pure-bred dairy cows, to the end that their character, quality, and value may be associated in the record with their pedigree. Then, any uninitiated purchaser even, may be able to know as much from a perusal of the record as any expert, and a cow's genealogy will be accompanied by an authenticated statement of the accomplishments of her progenitors. This seems to be all that is needed to make a record perfect, and we think it is a happy conception.

Science Applied to Farming, LIII

Economy in Cattle Feeding, Composition of Foods, Feeding Standards and Rations for Farm Animals.

In last month's *American Agriculturist*, page 497, was given a Table of "Composition, Digestibility, and Nutritive Values of Feeding Stuffs, from a larger one by Wolff in the German "Farmers' Almanac for 1880." That table gave the average amounts of the food ingredients, albuminoids, carbohydrates, and fats contained in different foods, and likewise the amounts of these that are, from feeding trials, estimated to be actually digestible. It is the digestible parts of the food that supply the wants of the animal, that are made over into flesh and fat, skin and bone, milk and progeny, and are used to produce heat to keep the body warm, and muscular power for work. It is with these, therefore, that we have mainly to do in feeding.

Feeding Standards.

Having noted how much of the nutritive ingredients our feeding stuffs contain, the next step is to learn how much of each different animal needs for maintenance and for production of meat, milk, work, etc. The German experimenters have studied into this matter very carefully, in two ways: first, by experiments, feeding animals with different kinds and amounts of food, and noting the effects; second, by observing the methods and results of feeding, as practised by the most successful farmers. On the basis of these two kinds of observations feeding standards have been calculated, as shown below. In brief, it has been found that full-grown oxen, at rest in the stall, can be kept for long periods in fair condition with food of such sort as to supply them, per 1,000 lbs. live weight, with 0.6 lbs. albuminoids, and 7.0 lbs. carbohydrates, in forms to be digested and taken into the circulation. It has been found well to have this supplied by 14-15 lbs. dry substance in the food. With rations furnishing these amounts of digestible ingredients, there has sometimes been observed a slight improvement, but perhaps oftener a small falling off in condition. It appears on the whole, better to increase the ration, so as to give 0.7 lbs. nitrogenous, and a little over 8 lbs. non-nitrogenous nutrients, with a nutritive ratio of 1:12. It seems to make little difference in what forms these are given, whether in hay, straw, oil-meal, or otherwise, provided the food be wholesome and palatable. These materials suffice to make up for the wastes of the animal's body, to keep it warm, and to produce the small amount of muscular power needed when the animal is at rest.

If, now, the ox is to be worked or fattened, food for production of meat or force is required. Or if, instead of an ox, we have a milch cow, she will need food for production of milk, in addition to what is necessary to maintain her body in good condition. And this food for production must be not only larger in quantity, but different in quality; it must have a larger proportion of albuminoids,—as the German's say, the nutritive ratio must be narrower. Thus Wolff recommends for a daily ration for milch cows, per 1,000 lbs. live weight, 2.5 lbs. digestible albuminoids, 12.5 digestible carbohydrates, and 0.4 lbs. digestible fats, with a nutritive ratio of 1:5.4. This is just about what would be contained in 30 lbs. of fine quality, young, cut hay, or 120 lbs. of young grass, either of which would make a very good daily ration for a milch cow. The following table by Wolff, from the "Farmers' Almanac" referred to, gives feeding standards for various domestic animals. The first column gives the total amount of organic substance—that is, the

whole food, less water and ash, in the daily ration. The next three columns give the amounts of digestible albuminoids, carbohydrates, and fats. The fifth column, "Total nutritive substance," is the sums of the digestible nutrients in the previous three columns. The last column gives the ratio of albuminoids to carbohydrates, or the Nutritive ratio.

Feeding Standards.

KIND OF ANIMAL, WEIGHT, AGE, ETC.	Total organic substance.		Nutritive (digestible) substances.			Total nutritive substance.	Nutritive ratio.

Practical Application. Calculation of Daily Rations for Farm Animals.

To use the feeding standards, let us take some of the feeding stuffs in the table last month, and leaving out of account the water, ash, and total amount of the ingredients, note the amounts of digestible ingredients, as shown in the condensed table below.

Digestible Ingredients of Fodder Stuffs.

KIND OF FODDER.	DIGESTIBLE FOOD INGREDIENTS.			Nutritive ratio.
	Albumi- noids.	Carbo- hydrates, including fibre.	Fat.	
I. HAY.	%	%	%	as 1 :
Meadow Hay, poor.....	3.4	34.9	0.5	10.6
“ “ medium.....	5.4	41.0	1.0	8.0
“ “ very good.....	7.4	41.7	1.3	6.1
Red Clover, poor.....	5.7	37.9	1.0	7.1
“ “ medium.....	7.0	38.1	1.2	5.9
“ “ very good.....	8.5	38.2	1.7	5.0
II. STRAW.				
Winter Wheat.....	0.8	35.6	0.4	45.8
Winter Rye.....	0.8	36.5	0.4	46.9
Oat.....	1.4	40.1	0.7	29.9
III. ROOTS AND TUBERS.				
Potatoes.....	1.1	22.8	0.2	21.6
Sugar Beets.....	1.0	16.7	0.1	17.0
Turnips.....	1.1	6.1	0.1	5.8
IV. MANUFACTURING AND WASTE PRODUCTS, ETC.				
Sugar Beet Cake.....	1.8	24.6	0.2	13.9
Malt Sprouts.....	12.8	51.6	1.7	4.7
Wheat Bran, coarse.....	12.6	42.7	2.6	3.9
Rye Bran.....	12.2	46.2	3.6	4.5
Linseed Cake.....	24.8	27.5	8.9	2.0
Palm Nut Ca.....	16.1	54.4	9.5	4.9
Cotton-seed Cake.....	17.5	14.9	5.5	1.7
Cotton-seed Cake, decort'd.....	31.0	18.3	12.3	1.6
Flesh Meal.....	69.2	....	11.2	0.4

Suppose now that I wish to feed my oxen that are standing in the stable doing no work, on

medium quality hay and oat straw, and add enough wheat bran to keep them in good store condition. By the above figures there will be contained in:

	Albuminoids.	Carbohydrates.	Fats.	Total.
6 lbs. medium hay.....	0.32 lbs.	2.5 lbs.	0.06 lbs.	2.88 lbs.
12 lbs. oat straw.....	0.17 lbs.	4.8 lbs.	0.08 lbs.	5.05 lbs.
2 lbs. wheat bran.....	0.25 lbs.	0.8 lbs.	0.05 lbs.	1.10 lbs.
Whole daily ration.....	0.74 lbs.	8.1 lbs.	0.19 lbs.	9.03 lbs.
Standard ration.....	0.8 lbs.	8.0 lbs.	0.15 lbs.	8.95 lbs.

That is, 6 lbs. of medium hay, 12 lbs. oat straw, and 2 lbs. wheat bran, will furnish just about the quantities of digestible albuminoids, carbohydrates, and fats, that the standard per day for 1,000 lbs., live weight, requires.

My friend and former assistant, Prof. W. H. Jordan, of the Maine Agricultural College, has made use of the feeding standards above given, in calculating the following rations for various farm animals. It is not meant that just these proportions must be used. There are wide variations in the composition, digestibility, and flavor of the same feeding stuffs. So likewise the individual peculiarities of the animals, their size, condition, varying capacities for digesting, and more especially, for their food, differ greatly. Hence the rations need to be adapted to particular cases. The important thing is to mix the foods on hand, or to be bought, so as to secure the best results at the lowest cost. These are simply examples of mixtures that contain the nutrients in about the proportions believed to be best adapted to the purpose. I cannot give what seems to me the right view of this system of calculating food-rations, better than in the words of a shrewd and intelligent German farmer, who has had considerable experience in their use: "As indications of what is best, they are invaluable; to follow them blindly would be folly."

Wesleyan University, Middletown, Conn.

## Fencing and Fences.

This important subject comes home to every owner of a farm or of a village lot that requires enclosure. At a meeting of New Hampshire farmers, several gentlemen publicly offered to sell their farms for less than what the existing fencing on them had cost. In a recent address at an Agricultural Con-

Fig. 1.

Fig. 2.

Fig. 3.

vention, Mr. A. W. Cheever, editor "N. E. Farmer," said he had carefully gone over the statistics of farms, animals, crops, and cost of fences, and found that: "It takes, on the average for the whole country, \$1.74 worth of fences to keep \$1.65 worth of stock from eating up \$2.45 worth of crops."

Nine years ago the statistics gathered at Washington showed that the fences then in existence, had cost \$1,747,549,931. The additions since have raised the cost of the present fencing of the country to fully **\$2,000,000,000**. A million dollars is a pretty large sum to count, or even to conceive of, (we can not count one million in the working days of a month, counting one a second and 10 hours a day), but here are two thousand such millions. The interest and repairs amount to over \$200,000,000 a year, and the rebuilding of decaying fences nearly as much more, making our annual fence tax far more than the entire cost of the Army, Navy, the General Government expenses and Pensions, together with the interest on the public debt.

In N. Y. State, for example, there are some 75,000 miles of roads requiring 150,000 miles of fencing, costing over \$40,000,000, and the total fencing in this single State has cost not less than \$230,000,000.

During 38 years past the *American Agriculturist* has had not a little to say as to the uselessness of a good deal of the fencing. But much will be needed wherever live animals are kept, and we propose now to direct some effort to reducing the cost of fencing generally. If this one item in the United States can be reduced only one-fourth, the saving will amount to \$500,000,000. In the older States, there are an average of about two miles of fencing

5.

Fig. 6.

Fig. 7.

Fig. 4.

Fig. 8.

for each 100-acre farm, costing about \$1 a rod, or \$640. If, in building new fences and replacing old ones, we can erect them at  $\frac{1}{2}$  to  $\frac{1}{4}$  the cost of the present fences, and have those that will last two, three, four or more times as long, and require

but small annual repairs, the average value of farms will be enhanced some hundreds of dollars at least. If a narrow effective fence can take the place of the ordinary "worm fence," there will be a great decrease in the production of weeds and foul plants. Two miles of such fence on a farm, occupying a strip  $8\frac{1}{2}$  feet wide with its projecting corners, wastes two full acres of ground, worth \$150, or more. The cost of Iron, and recently of Steel, are greatly reduced, and they have come into very largely increased use in ship-building, house-building, etc. Why should they not take the place of wood in all varieties of fencing, both for posts and rails? Such a change is already rapidly taking place.

More than 100,000 miles of Barbed Wire Fence have been recently erected. Whether this style of fencing is best, or desirable; whether it is too barbarous or not, for general adoption over our vast, timberless prairies at the West, and what forms can be adopted in our more thickly settled regions, for highway fences, for village lot enclosures, etc., will be the subject of examination and discussion in this and especially in future papers.

### A Call for Information.

Many of our readers have the new barbed fences. We earnestly invite accounts of their experience and observation, *pro* and *con*. We have some letters denouncing barbed wire fences as too cruel to be permitted, and insisting that they should be prohibited by law along highways and railways. Others speak of their introduction as of inestimable value. Let us have all possible testimony on *both* sides of the question. Also any information and suggestions about iron posts.

### Iron Fence Posts.

As there is a pressing need of new and improved forms of Iron Fence Posts, in order to call out information and stimulate invention in this direction, we will first briefly introduce this branch of the subject, by giving illustrations and descriptions of a few of the forms that have come under our own notice.

Fig. 9.

Fig. 10.

The simplest form is an iron bar, or an iron tube, with holes or staples for attaching the horizontal wires. The same weight of iron is stronger in the form of a tube than in a solid bar. But cast-iron will be likely to be used generally. After securing sufficient strength of post above ground, the next points to be aimed at are *light weight*, on account of expense, and breadth of resisting surface in the soil to prevent swaying in any direction. Non-liability to heaving by frost is also an important point.

And just here we will introduce a matter referred to by a correspondent, who writes that a fatal objection to all forms of wire or barbed wire fence for uneven ground, is, that when the fence runs across a hollow or depression of the surface, as in figure 1, the contraction of the wire by cold lifts out the lower posts, as indicated in figure 2, even if the depression be only 2 or 3 feet, if the wires are tight. We suggest, as a remedy, two independent posts together at the lowest point, as shown in figure 3.

### Various Forms of Iron Posts.

Andrew Turner, of Bellona, N. Y., writes us, describing a form of iron post, of which the exact form is not quite clear. He gives one suggestion that may be useful wherever there are plenty of stones of *so soft a texture as to be easily drilled*. During winter, or other leisure seasons, he drills holes in them of a size to admit the foot of the iron post, of whatever form, say 6 inches in depth. The stones are put into the ground any desired depth, and the posts inserted. The posts may then be of

any iron pipe. We suggest using flat stones 3 to 6 inches thick, and drilling the holes *through* to let the posts extend some distance into the soil below.

John Cunningham, of Luzerne Co., Pa., sends us sketches of an iron fence post devised by him, to

Fig. 11.

be made of cast or rolled iron, with double angles, as shown by the cross section at figure 4. The post, shown in fig. 5, has holes for 4 or 5 wires. The holes are made so as to receive the wires which are held fast by a key—in this case a

common nail of proper size, driven above the wire. To prevent loosening by contraction and expansion of the wire, we suggest driving a nail from *each* side, one above and one below the wire.

An iron post made by the Iowa Barbed Wire Fence Co., is shown at fig. 6. The bar of iron is  $\frac{1}{2}$  inch thick and about  $2\frac{1}{2}$  inches wide, curved so as to stiffen it, (fig. 7). The wires are held on the outer curved side by staples over them to be clinched on the concave side. To hold the post firmly, a disc, (fig. 8), is sunk in the ground at any desired depth, and the post driven through the curved opening in it made to just fit the post. This disc is of  $\frac{3}{16}$  inch iron, 6 inches in diameter, besides the edge of it, which is turned down  $\frac{1}{4}$  inch all round.

J. C. Taylor, of Chicago, has an iron post (fig. 9) of similar construction to the above, but strengthened by a flange in the curve. This is driven into the ground without any boring. The method of attaching the wire is shown in the small cross section engraving at the top of figure 9.

The Bullard iron fence post (fig. 10), made by the Washburn & Moen Manufacturing Co., is a flat bar slotted on one edge to receive the wires, and held by a forked brace driven into the ground.—Brick tiles of the form shown in fig. 11, are also used as support to strengthen this post.—The same company make a post of angle iron (fig. 12) which is braced in the line of strain. The wires are clamped by a keyed sliding holder, shown in figure 13.

Fig. 13.

### The Barbed Wires.

Many attempts have been made to imitate the natural thorn-armed plants, by affixing barbs to wire, and over 30 different patterns have been devised. We have some 25 specimens, the exact size and form of which are shown in the engravings below. Nearly all the fence wires here described, are now made of Steel, and most are supplied either painted (or japanned), or galvanized (coated with zinc). They average about 1 lb. per rod per wire, and usually cost 9 to 13 cents per pound.

The engravings are so exact that our readers can almost decide and make their own selection. We confess to being yet in the condition of a learner—but an earnest, investigating one, in behalf of the public. We started with a prejudice against any of the severer forms of barbs; yet some manufacturers say the demand is for the longest barbs, especially at the far West. We intend to learn more and say more on this, especially when we hear further from our readers experienced in their use.

No. 1 is probably the first attempt at "barbing," said to have been made by an Iowa blacksmith, some 20 years ago.

It is a common horse-shoe nail bent around the main wire, and held in position by binding it with a small wire, as shown.

No. 2, the "Cleveland Barbed Wire." The points stand out at nearly right angles, which could not well be shown in the engraving perspective.

The same barb can be applied to double or triple wires. The names of the manufacturers unknown to us.

No. 3.—Engraved from a specimen; distinctive name unknown. These barbs also stand out at

right angles, that is, in four directions. We are not aware that this form is now being manufactured.

No. 4, the "Kelly Steel Barb Wire," with the two-point barb stamped or cut from sheet metal, and pierced to string upon one

main wire and be held in place by the other. This variety is manufactured by the "Thorn Wire Hedge Co.," we believe.

No. 5, "Roberts Barbed Wire," engraved from specimen; if now manufactured, the makers are as yet unknown to us. The two-pointed barb is

a cast double-pointed piece of metal, with a deep groove around its middle, where it is grasped and held somewhat firmly by the twisted main wires.

No. 6, the "Crandall's Barbed Wire," is simple, and this barb may probably be put upon a single wire, like No. 2, but when there are only

two barbs, they need to be set closer together than for the four barbs. Made by the Chicago Galvanizing Co.

No. 7, the "Sterling Barbed Wire," has a single pointed wire bent firmly around one of the main wires, and locked over itself; it

presents the two barbs, pointing in the two opposite directions. This wire is manufactured by the North-western Barb Wire Co.

No. 8, the "Bronson Barbed Wire." The two barbs are

formed by cutting one of the running wires, and bending and locking the ends. We do not know the manufacturers.

No. 9.—The "Glidden Steel Barbed Fencing." The barb has a close double turn around one of the main wires.

To reduce the objections to dangerous points, this variety has for some time past been made with the barbs materi-

ally shortened. Manufactured by the Washburn & Moen M'fg. Co., as per advertisement elsewhere.

No. 10, the "Three-pointed, Stone City Steel Barbed

Wire," has a 3-pointed piece locked between the two main wires. Made by the Stone City Barb Wire Fence Co.

No. 11. "The Steel Barbed Cable Fence," (Frentress' & Scutt's patents), is similar to No. 10, but with 4 barbs

on one solid piece. Made by the Illinois Fence Company. Two other barbs, somewhat similar to these, are made by H. B. Scutt & Co.

No. 12. "Spiral Twist, 4-pointed, Steel-barbed Cable Fence Wire"

(Watkins' patent). The barbs are on one solid piece of metal, which is bent to conform to the twist of the main wires, and is thus held fast. Made by Watkins & Ashley.

No. 13, the "Quadrated Barbed Fence," is explained

by the engraving. It has well-fastened barbs certainly. Made, we believe, by Pittsburgh Hinge Co.

No. 14. The "Iowa 4-pointed Barbed Steel Wire," (Burnell's patent). The form and structure are plainly shown in the

engraving. The wire of the barbs passes twice around and between the main wires, but so loosely as to yield a little. It is made by the Iowa Barb Steel Wire Co., both in Iowa and New York, as advertised elsewhere.

No. 15. We give the name "Lyman Manufacturing Co. Barbed Fence" to this, from

the Company reported as manufacturing it. Its form is shown in the engraving.

No. 16. The "Allis Patent Barb," is all the name we have heard for this. Our specimen is a solid

piece of the form shown in the engraving herewith.

No. 17, the "American Barb Fence." A central, wire closely sheathed with a continuous metal strip, with its edges cut in the form of barbs, turned out in all directions, the points one inch apart. The

whole is covered and saturated with paint or zinc, firmly cementing the outer and inner metal. Made by the American Barb Fence Co., (J. C. Taylor, General Agent), as advertised elsewhere.

No. 18, the "Brinkerhoff Steel Strap and Barb," of the form and size shown in the engraving. Weight

about 1 lb. to the rod. The barb is fastened, as shown on the reverse side of No. 19, and the whole is galvanized, which firmly solders the barb. Manufactured by the Washburn & Moen Mfg. Co., as advertised elsewhere.

No. 19, we call the "Brinkerhoff

Improved." This is the Brinkerhoff strap, same as No. 18, but the barbs, which were prepared in this form at our suggestion and request, project only about one-fourth of an inch, and the edges are so inclined that they will not catch and tear the skin of animals unless pushed horizontally under heavy pressure, nor will they injure clothing swinging loosely against them.

Others claim strongly that the barbs are not long enough or sharp enough to repel cattle. That is one of the points to be decided. Indeed, the leading question in the discussion now is, how much, or how little harbing is best, taking into account effectiveness, and safety for animals. No. 20 is a partial section of No. 19, which is introduced to show how it is twisted in putting up.

No. 21 is from the actual piece we brought from a fence at Beloit, Wis., (sketched from memory last month, not quite correctly). Objec-

tionable from its too sharp barbs, and the expensive waste of cutting out the metal between the barbs.

No. 22. "Scutt's Patent Tablet Wire," provides a row of wooden blocks on the middle or top, large

enough to be readily seen by animals approaching.

No. 23. "Scutt's Lock Center

Barb," a modification of No. 11, as is shown by the engraving.

Nos. 24, 25, 26.—"Lord's Rotary Barbs." The engravings show three different forms of these, in which the barbs are arranged to turn or revolve

loosely in the wire. The claim is that they yield to the motion of the animal, and lessen the tearing. Some other forms will be shown next month.

# A House Costing \$4,000, Complete.

BY S. B. REED, ARCHITECT, 245 BROADWAY, N. Y. CITY.

This plan is for a commodious, convenient residence, economically constructed with appliances for heating, ventilation, water, etc., complete....

**Elevation.**—(Fig. 1.) The outlines are irregular,

Fig. 1.—FRONT ELEVATION—FACING EASTWARD.

and agreeably conform to the site for which it is planned—an elevated, undulating and picturesque point, fringed with forest trees, and overlooking the waters. It fronts eastward, bringing the Conservatory on the warm, or southern side. The position of the tower, and its size, make it a prominent feature, and very valuable for an elevated outlook commanding extensive and interesting views. The aim is to have the exterior ornamentation neat and effective, and being mostly of open timber work, is simple of construction. The inclined grounds to the right bring most of the foundation above ground, and gives good sized openings to the finished basement....

**Cellar and Basement.**—(Fig. 2.) Height of walls in main part 7 feet; in the kitchen end 8 feet, when floored 7 feet. That under the main part is for cellar purposes, to contain the furnace; bins for fuel and vegetables, with six small windows for light and air. The kitchen cellar part is floored and plastered, well lighted, contains a range, boiler, sink, wash tubs, and a force-pump. The pantry adjoining the kitchen is shelved on three sides, and has a dumb-waiter leading to the dining-room pantry above. The outside entrance to the kitchen and cellar is by the area at the rear. A convenient stairway leads from the front entry in the basement to the rear entry in the first story.... **First Story.**—(Fig. 3.) Height of ceiling in main part, 10 feet;

Fig. 2.—PLAN OF BASEMENT.

in the wing 9 feet. The principal entrance has double front and vestibule doors, to a large hall, 9½ by 18½ feet. Small closets at each side of the

vestibule serve for umbrellas, overshoes, etc. At the left, double doors, leading to the parlor, and further on a door leads to the library, at the right, one to the dining-room, and one at the rear, to the back entry. The parlor is of ample size, and adjoins the library through sliding-doors. Each of these rooms has hard-wood mantels, is well lighted from without by large windows, and both have sash-doors leading to the conservatory. The latter is finished with a concrete bottom, and altogether costs but \$150. By a little effort at selection and arrangement of plants, this apartment may be made a constant source of interest and pleasure. The dining-room has outlooks in three directions, and communicates directly with the porch, hall, the rear entry, and a pantry having a dumb-waiter to the basement. The rear entry is cut off from the main hall (to save the latter from much common use and wear,) and has a wash-bowl, and stairs leading to the basement. The rear porch, and dining-room pantry are both under a roof similar to that shown for the front piazza; the pantry extending to the outer face, forms an alcove of the porch. The main stairs to the second story are of the "quarter circle" pattern, with niche near the top, and have a 10-inch panelled newel; a 2½ by 4½-inch moulded rail; and 2½-inch fluted ballusters, all of hard

wood.... **Second Story.**—(Fig. 4.) Height of ceiling in main part 9 feet; in wing 8 feet. The divisions are: a hall, three chambers, a bed-room, bath-room, and six closets, all of ample dimensions. Mantel shelves with trusses of hard woods are put in each chamber. The stairs to the

Fig. 3.—PLAN OF FIRST STORY.

attic are placed above those of the first story, which are thus made continuous to the upper hall. .... **Attic.**—(Fig. 5. Height of finished ceiling 9 feet. This is divided into a hall, two chambers, a bed-room, and two closets. The stairs to the tower are "boxed in" with narrow, double-dressed beaded ceiling, and have a panelled door at the foot.... **Tower.**—Size of floor plan (not shown), 9½ feet square. Height of side walls to top of plate 6 feet, and continued along the under side of the rafters at an angle of 45° to the ceiling, which is 9 feet high. The boxing of the attic stairs extends 2 feet above the floor, and has a moulded cap along the top.... **Construction.**—Foundation walls of hard brick and good mortar. Cellar bottom is levelled with concrete. The frame is of seasoned spruce. Inclosing of first quality pine clap boards laid on felt and dressed sheathing. Roofing of "Chapman" slate, laid on tarred felt and sheathing. Gutters and leaders of IX tin. Floors of narrow spruce. Plastering, three coats, hard finished. Casings and mouldings of clear pine. Doors all panelled and moulded. Sash of best make, four lights to each window, and hung to balance weights. Blinds to each window above the foun-

dation; shutters to kitchen windows. Painting, two coats of best materials. The hard woods oiled. Plumbing; the tank (not shown) placed in the hall of the attic, just over the bath-room, is 3 by 4 by 6 feet, lined with lead; bath-tub, seat-closet, and wash-bowl in rear entry; range, boiler, sink, wash-tubs, and a force-pump in the kitchen; all connected with proper lead pipes for hot and cold

Fig. 4.—PLAN OF SECOND STORY.

water. A 4-inch soil-pipe leads from the bath-room to a 5-inch drain of vitrified tile pipe conveying all waste to a cesspool 50 feet from the house. The soil pipe is ventilated by a pipe leading from it to above the roof with a T connection at the top. The heater is inclosed with brick, and has pipes to convey warmed air to the halls and rooms of the first and second stories. Bells from the front door to the rear entry; and from the second story hall to the attic and kitchen, are put in with wires passing through tubes concealed from sight. Speaking-tubes are put in, leading from the dining-room to the kitchen. The contract requires all done in a workmanlike and substantial manner, and of materials best adapted to their several purposes.... **Cost.**—Any one at all familiar with building, will, by going over the following items of cost, learn the character of this house. The total of these items might easily be doubled if desirable, without changing the plans in the least, simply by increasing the expense in the details of finish. Whenever employed to prepare plans, my first inquiry is as to the amount to be appropriated for building, then to ascertain the accommodation required, the facts as to site, learn all I can of the characteristics, and tastes of the owner and his family, then prepare plans to meet the requirements, without exceeding the amount set down to be expended. Cost of materials and labor, viz.:

### A Distinguished Immigrant.—Professor Baird's European Carp.

In 1876, Professor Baird, U. S. Commissioner of Fisheries, having for a long time understood the importance of acclimating the Carp in this country, engaged an eminent German fish-culturist, Dr. Rudolph Hessel, to bring over a supply of the best varieties of this favorite European food-fish. The first experiment, in May, 1876, was unsuccessful, owing to the extremely high temperature encountered on the passage, and out of 300, with which he started, only four survived. Another unsuccessful attempt was made in December of the same year, and seven more were brought from Hungary, a large number having died on the passage. In May, 1877, Dr. Hessel returned from a third trip, bringing to New York 345 young carp, 227 of which were of the varieties known as the "Leather Carp" and "Mirror Carp," and 118 of the common or "Scale Carp." The U. S. Fish Commission was not ready to receive them, and they were placed for a time in ponds prepared for their reception in Druid Hill Park, Baltimore, under the superintendence of Major T. B. Ferguson, Maryland Commissioner of Fisheries. Here they thrived and increased rapidly in size, and in May, 1878, one hundred and twenty were removed to the Government Carp Ponds, built for them on the Washington Monument Reservation, in the City of Washington. These ponds, a plan of the essential portions of which is given below, are constructed after the best German models, and cover about twelve acres of land, in the vicinity of the Washington Monument.

The Carp have now multiplied to such an extent that it is possible to begin the work of distributing them, and, by the time this number of the *American Agriculturist* reaches its readers, Prof. Baird's messengers will have carried cans of young carp to all parts of the United States. The introduction of this new food-fish will be of great interest and importance to all inland communities, for there is no ditch, pond, or mill-dam, or any boggy, muddy spot, which can be converted into a pond, in which they will not thrive. It will be strange if, within twenty years, carp do not become as common domestic animals as ducks or pigeons. Through the courtesy of Prof. Baird we are able to present an excellent engraving of the new fish, with which, before long, many of our readers will doubtless become more directly acquainted.

The Carp belongs to the family known to natu-

alists as the *Cyprinidae*, members of which are to be found in every stream and pond in North America. Good examples of this family are the common Goldfish, and the familiar brook species known everywhere by such names as "Dace," "Chub," "Red-fin," "Fall-fish," and "Shiner." The "Buffalo-fish" of the West is also said to resemble it in many respects. The Carp, however, is the

and has a thick, soft skin, which is velvety to the touch. Both the latter varieties are said to be much superior to the Scale Carp, which is best known, in flavor, hardness, and adaptation to confinement. A claim has been made that carp were introduced into America, and particularly into the Hudson River, many years ago, but this is quite unsubstantiated.

The Carp has other and strong recommendations:

*It is, of all fish, the most readily propagated and reared. It has been domesticated in Europe from time immemorial, having been introduced many centuries ago from Central Asia or China, where it is native. Carp soon become tame and eat from the hands of their keeper; Dr. Hessel handles those in the Government ponds as if they were tame kittens, and says that they come to him when he whistles. Their fecundity is great. A fish weighing four or five pounds lays 400,000 to 500,000 or more eggs, and one of ten or fifteen pounds*

Fig. 1.—THE EUROPEAN CARP (*Cyprinus carpio*.)

king of his tribe, and those who know, do not hesitate to say that, as a food-fish, it far excels the best of them. "In Paris, Berlin, and Hamburg," writes Dr. Hessel, "in spite of an abundant supply of different salt and fresh-water fishes, the carp is always preferred to these, and, with the exception of the trout and salmon, it frequently commands a price three times as high as that of all the rest." Artificial culture, continued through many centuries, has developed in the carp a number of varieties, as strongly marked as those of sheep, dogs, pigeons, or other domestic animals. These are divided into

about 1,500,000. In Middle Europe they spawn from May to August, and the breeding season appears to be nearly the same in Washington: In 1879 they spawned here from June to September. The eggs are sticky, and cling to plants and twigs, hatching in from nine to eighteen days, according to temperature. The actual rate of increase is very great, owing in part to the fact that the parents do not devour their young. The 120 fish brought to Washington two years ago have increased to, at least, 20,000. *It is thus able to populate a body of water to the fullest extent, filling up the available*

Fig. 2.—PLAN OF GOVERNMENT CARP POND, WASHINGTON, D. C.

A, B, C, D, E, and F, Hatching Ponds; G, Turtle Pond; H, Watch House; J, East Pond; K, North-west Pond; L, South-west Pond; O, O, Outlets; P, P, Fountains.

three groups: the "Scale Carp", which most closely resembles the original form, having scales like ordinary fishes, and has four thread-like appendages, or barbels, under the chin; the "Mirror Carp" has extraordinarily large scales, which run along the side of the body in three or four rows, the rest of the body being bare; and the "Leather" or "Naked Carp," which is almost destitute of scales, having only a few along the line of the back,

*inhabiting the same waters.* "The food-fish indigenous to the United States," says Prof. Baird, "which has been most widely distributed in the smaller ponds and lakes, is the Large-mouthed Black-Bass. This fish is very carnivorous, preying upon almost all species in the same waters. Even the Pickerel is said to decrease rapidly when in contact with it. The necessity for fish-food is always a bar to a great increase of numbers among fishes, particularly in

space with their own kind, while carnivorous species require that a large number of other fishes on which they may prey inhabit the waters with them. Unlike the majority of American food-fishes, their diet is largely vegetable, and they are particularly fond of water-cresses and other juicy plants. They grow fat upon the *algæ*, commonly called "Frog-spittle," which covers quiet waters. They also devour worms and insect-larvæ, which they root out of the mud, and all kinds of refuse matter, such as the offal of kitchens, slaughter-houses, and breweries. By reason of these habits, *they are harmless to other fishes*

small bodies of water." Carp, on the other hand, introduced into new waters, fills a vacancy, and not only do not decrease the number of other fishes, but by supplying them food, enable the existence of a large additional number of carnivorous fishes.

*The Carp is adapted to very varied climates, and will thrive under conditions unfavorable to any equally palatable American fish.* They are equally at home in lakes or streams, and in the merest puddles and ditches, and are found in the latitude of St. Petersburg as well as in Italy and Northern Africa. It is believed that they will excel all others for propagation in ponds and other sluggish waters north and south, now either barren of life or inhabited by a limited number of pickerel, cat-fishes or sun-fishes.

*It is very hardy in all stages of growth.*—"The Carp is able," says Dr. Hessel, "to live in water where other fishes could not possibly exist—for instance, in the pools of bog-meadows or sloughs."—Though it is not to be inferred from this that the best Carp-ponds should be thus located. In Silesia, puddles two or three feet deep, in the villages, are used for raising two-year-old Carp for stocking distant waters. From this resource a single estate realized what would amount to about \$55 to the acre of pond surface. In Europe, Carp are always taken to market alive, in tanks or barrels, and, if they are not sold, returned to the water alive at the end of the day. They are said to be kept alive in cellars in the winter, wrapped in wet moss and fed upon bread soaked in milk. Dr. Hessel once kept one this way five weeks. In cold climates they protect themselves from freezing in winter by retiring in groups of 50 to 100 or more, into cavities in the muddy bottom called "kettles," where they pass the time until spring, huddled together in concentric circles, with their heads together, the posterior part of the body raised and held immovably, scarcely lifting the gills for breathing and without taking a particle of food. This abstinence and torpidity lasts in cold countries six or even seven months, and thus they can live out a very rigorous winter.

*Its growth is very rapid.*—Dr. Hessel says that in Central Europe its growth is entirely suspended in the winter, the increase in weight taking place from May to August, and especially in July. The rate of growth depends upon many things—the temperature of the water, the quality and quantity of food, the nature of the bottom. In rivers and lakes they attain the greatest size. The rapidity with which Professor Baird's fish have grown surpasses anything hitherto known, and indicates that the Carp is particularly well adapted to America. The normal weight to which the Carp may attain in three years in Europe is an average of three to three and three-fourths pounds; that is, a fish which has lived two summers, and is eighteen months old, will weigh from two and three-fourths to three and three-fourths pounds in the year following. Dr. Hessel states that the Washington Carp, four summers old, now weigh nine or ten pounds; those of the same age in Europe would not weigh more than four; those three summers old weigh about three and three-fourths or four pounds, while the best in Europe of the same age weigh about two pounds.

**Large Farms.**—Most people are attracted by the show of a great business, and the desire to extend operations is very general. But a man who can successfully manage 100 acres, may not be able to run a 500 or 1,000-acre farm, and many men who can profitably work a farm by their own labor, fail when they try to do so by hired help. To so manage a number of working men that every hour's work of each shall be made to concentrate upon one desired object, requires much ability. For want of this, many who have become "well off" on a small farm, have failed on a large one where they have had to employ help. A man may be worthily ambitious of success in business, but before he leaves a small farm, for one much larger, he should be satisfied of his ability to manage it. It is not a new thing for a man to be land-poor, even though the land itself is of good quality. As with extensive and overgrown nations, large farms might sometimes be of more value to all concerned if they were divided up and each part put under a partial or entirely separate management.

## Among the Farmers.—No. 48.

BY ONE OF THEM.

### How Butter Goes to Market.

Almost all over the country butter which is made in farmers' families in excess of their requirements, goes to the country store in exchange for sugar, tea, coffee, and spices. It is, of course, of all colors and textures and qualities, usually wrapped, or partially wrapped, in old and well-worn muslin, upon which, if "seam and gusset and band" are not apparent, the suspicion of them is. It is in lumps of ovoid form, usually weighing one to three pounds. The country store-keeper selects the best for his own immediate sales to village people; the rest is graded and packed, according to color and quality, in "Welsh tubs," or whatever other package will best suit the market. An enormous quantity of butter finds its way to market in this way, and forms the lower grades. Such butter can not be depended upon to keep, unless, indeed, the grading and repacking be done with extraordinary care; then it may prove tolerably good.

Among farmers who are really dairy folks, the butter is packed for market as soon as it is made. The expense of tubs, or pails, and firkins, (and these words are used technically with rather forced significations,) is considerable. What are known as

### "Welsh Tub" s

are ash, oak, or spruce pails, without bails, but with close covers. They hold, usually, 20, 30, and 50 pounds. These are the most convenient packages for shipping to a distance, because they are not to be returned; and though they cost only about a cent a pound for the butter they contain, yet dairy folks find it cheaper to pack and ship their butter in "return pails" of some kind. These are of a great variety of styles and sizes. The common, and, as a rule, the best size, is the 50-pound package. It usually holds several pounds more, but not the regular 56 pounds, which is a "firkin" in Great Britain. Shipping tubs, holding just this weight, are coming into use somewhat. But the notion is growing that it is best to adhere to the decimal system, and ship abroad in tubs that will hold but 50 pounds, and in what we call *firkins*, that is, in kegs holding 100 pounds. These packages are of oak, and are very strong and neat, and are brine and butter-tight in all weathers and climates; I may add air-tight, also, for so they are, in the general acceptance of the term.

These packages are manufactured where lumber of the best sorts is accessible, and the trade requires an enormous quantity in the aggregate, especially since much lard is packed in them, or in packages closely resembling those used for butter.

### "Fancy Butter" Packages

are, of course, of many forms, as each maker wishes his butter to be both attractive and unique. All "print-butter," or butter in small packages marked with the name of the maker, is properly regarded as "fancy," whether it bring a higher price than other good butter or not. Still, it ought to be good enough to sell higher than good tub or firkin butter.

Philadelphia has long been famous for its excellent print-butter. This is generally put up upon the common hand stamps (fig. 1) in pound "pats," which may have either of the two forms represented by the dotted lines. Simple devices, such as a

Fig. 1.—HAND STAMP.

sheaf of wheat, roses, pineapples, acorns, and oak leaves and non-descript leaves are common. Monograms or single letters are not rare, with occasionally a more elaborate device. These "pats," for they are patted into form upon the stamps, are marketed in what are known as Philadelphia tubs, which are oval tubs of cedar, lined with tin, and having ice chambers in each end, having a nearly rectangular space in the center, in which the butter is packed upon shelves 2½ to 3 inches apart. Butter packed over

night, the ice chambers being filled with a freezing mixture, and refilled in the morning with simple ice, will go 48 hours in ordinary summer weather without softening. The covers lock down, and the tubs are often cased in quilted or felt jackets.

A good deal of butter is now made in rectangular (square or brick-shaped) prints, and shipped in

Fig. 2.—THE PHILADELPHIA BUTTER TUB.

these Philadelphia cedar tubs (fig. 2), or in square packages, with provision for ice in hot weather. One of the neatest of these is known as the Lancaster package. Its peculiarity is that tin cups, or boxes of tin, are provided for each print of butter, the prints being wrapped in pieces of muslin. The advantage offered by this package is, that the prints do not become marred in the hands of careless shippers and carriers, as is frequently the case.

One of the most ingenious applications of the new kind of veneering, cut in a continuous ribbon

Fig. 3.—BRADLEY'S BUTTER BOXES.

round and round the log, is the making of butter packages by the Bradley process. This is protected by several patents, and consists in sewing the bands of wood together, so as to make the sides of round (cylindrical) boxes or flaring pails, adapted to hold butter and similar articles, by having bottoms and covers attached by means of tin bands. Figure 3 shows a stack of these boxes, holding from ½ lb. to 10 lbs. They are made of spruce or of oak, and bear scalding in whey, and in brine, if desired, although these woods are so nearly tasteless that anything more than simple scalding seems unnecessary. These boxes are very strong, and inclose the butter nearly air-tight. They are made to be packed full of

butter, a disc of wax paper or piece of muslin being laid over the butter. When the butter is to be used, the cover is removed, and the seam is ripped with a penknife, when the package may be opened and taken off from the butter, which is left in a solid cake. Figure 4 shows the crate in which these packages are packed, the whole being furnished at the low cost to the

Fig. 4.—CRATE FOR SHIPPING.

consumer of one cent per pound for the butter which the crate will hold. The pails (fig. 5) may be used for butter also, but are also well adapted for lard, oysters, sausage meat, etc., and both the pails and boxes are furnished, when so ordered, both water and grease tight by being dipped in hot paraffine, which is absolutely colorless, odorless, and tasteless, and insoluble in water or cold fats, and penetrates both the wood and the seams and joints.

### The Burchard "Knock-down" Package.

This is also a new package, and it seems so well

adapted to its uses that it is sure to become popular. The term "knock-down" does not signify that this is a perfect *stunner*, but that it comes to pieces in such a way as to be packed in a small compass, and be readily reconstructed. It is intended solely for pound and half-pound rectangular prints, and as the butter in the case occupies but little more space than without, it admits of very close packing. Easy inspection, convenient delivery to customers, and perfect protection from the dangers of careless handling, are the objects supposed to be accomplished. Figure 6 represents a box holding one pound, with a paper gummed label about it, stating the name and address of the maker of the butter, and the dates at which it was made and shipped. The label being cut, the lid lifts off, and the box opens at any angle, as shown in figure 7, leaving the butter by itself in its wrapping of muslin or

Fig. 5. BUTTER PAILS.

#### Wax Tissue.

This article, by the way, is a very neat and beautiful thing for many purposes. It is simply fine tissue paper, saturated with paraffine, thereby rendered water and grease-proof, as well as air-tight. If the butter wrapped in it be kept cold and be dry when wrapped, the paper is easily removed, but if warm or wet when wrapped, then the paper sticks to the butter of course—for the nature of the butter is not changed, and being long in contact with moisture softens the paper. When used with discretion, it is far preferable to muslin for wrapping print-butter, and much cheaper, and may be left in contact with the same indefinitely without harm to it.

Fig. 6.—THE PACKAGE.

#### The Dollar a Pound Butter,

much of it comes to market in paper, that is, paste-board, boxes, without covers, and wrapped in muslin. This is the plan followed at Echo Farm, and Mr. Starr's imitators. These boxes have the following, or an equivalent, printed upon them; "This butter must not be left in this box or nap-

Fig. 7.—THE PACKAGE KNOCKED DOWN.

kin, but put in a cold place, but not in contact with ice, nor near any meat or vegetables." Long contact with the wet "napkin" is supposed to hurt the color of the butter, and to impair its flavor also. Close wrapping in the Wax Tissue has no such influence, but preserves the butter practically air-tight, and even though placed in the family "food safe," or ice-box, the flavor is not affected. The butter in these paper-boxes is placed in cases upon shelves, or in layers, separated by thin boards; in hot weather, space being left for a can of ice, and so shipped under lock and key.

#### Tin Shipping Cases.

I have two other butter packages to describe at present. One of these is quite new—a stout hand-pail, holding perhaps 14 quarts, but adapted to the

size of the round prints which it is to carry, is provided with large muffin rings, which will just take in a "pat" of butter, and are high enough to protect the device upon the print. Three or four of these are placed in a layer, and one layer is placed upon another, separated by a disc of tin, while the bottom layer rests upon a stout disc, strengthened by a ring, and having a stout wire coming up from it as high as the edge of the pail, where it is turned into a ring to lift out the whole contents at once. The top layer is covered by a disc of tin, which is held in place by the rim of the cover. Figure 8 shows this pail, which is well adapted to sending small quantities of butter short distances in summer, or any distance in cold weather. A heavy iron ring protects the bottom, and a lock and chain, such as are used upon milk cans, makes all secure. In warm weather it would be well to jacket the case, when the butter, if started cold, would not soften for nearly 12 hours. The

Fig. 8.—TIN SHIPPING CASE.

"Norton Butter Shipping Case."

Circumstances lately recalled to my mind a shipping case for butter, which I saw in use many years ago, by the late Mr. John T. Norton, of Farmington, Conn., and which I learn is still used by the Farmington Creamery Co., under Mr. Edward Norton's management, and more or less by other parties. I give you a sketch from recollection (fig. 9). The case holds 50 lbs. in summer, and 60 lbs. in winter, but might be made smaller. The butter is held in pans, with perpendicular sides, having a narrow rim, turned in at the upper edge. Each pan holds ten pounds, in balls or prints, and one pan rests upon another. They are placed in a heavy tin cylinder, like the body of a railroad milk can. At the top a pan for holding ice is placed, with its rim resting on the rim of the outer case, and this is covered by a double pail cover, with a handle, through which the chain is passed, by which the cover is locked down. The case has handles like a milk can, a heavy iron hoop at the bottom, and at the top, and is shipped jacketed in felt, covered with stout, colored muslin. The handles come through the jacket. The effect of the ice is distinctly perceived in the lowest pan, and the case is a very strong one, and not liable to damage, as handled by the "gentle" express and railroad hands.

Fig. 9.—THE NORTON CASE.

**Railroads vs. Farm Stock.**—The thousands of miles of railroads now in operation in the United States, and the many more to be built, makes the subject of the killing of farm stock, by passing trains, a practical and important one. Under the existing laws, railroad companies are required to either fence both sides of their roads, or to provide an equivalent barrier, and to maintain cattle-guards at all crossings; the corporations are only released from damages done to stock when all such fences and necessary measures are taken to keep stock from their tracks. If the track is thrown open at any point, not from public necessity, the

company is liable for damages. The fact that the owner of the stock has not taken any pains to keep his cattle out of danger, does not relieve the railroad corporation of its obligations to provide barriers.

#### Grain Mills to Order.

One need not be very old to be able to remember when the erection of a mill, even the simplest, for merely grinding corn, was an important event. There was much calculation beforehand, as the work of many different persons was required, a great number of parts was to be provided from various sources, and all, finally, with much trouble, brought together, and adapted to one another. After much disappointment and many delays, the mill was started; yet the mill was worth all the trouble it cost. From the moment it was completed, the locality rose in importance, and became a center to the neighborhood for many miles around. It made every farm within a wide circle more valuable, for

NORDYKE &amp; MARMON GRINDING MILL.

however successful the farmer in raising good crops of Indian corn and wheat, they must first go to the mill before they could be utilized. At first we had wind-mills and water-mills, and then mills independent of either wind or water, being worked by steam, but whatever the motive power, the making and bringing together of all the varied parts of the mill itself and its accessories remained a work requiring both forethought and time. It is not surprising in the general improvement in all agricultural machines that the mill, that most important accessory to the farm, should have kept pace. It used to be said, when parts of Maine were noted for their activity in ship-building, that ships were built by the mile, and cut off in lengths to suit purchasers. In a similar manner, one can now order a mill of a given capacity, and receive it, motive power, mill, and all complete, to the last nut and the wrench to turn it with, in a very short time. Rarely have we examined a catalogue with so much interest as we did that of the Nordyke & Marmon Co., of Indianapolis, Ind.; it is, in fact, a treatise rather than a catalogue, having 175 large pages, and so full of illustrations that a friend with strong mechanical tastes much desired to possess it for the beauty and variety of its engravings of machinery and parts of machines. As motive powers, various steam engines are described and figured, and the manner of utilizing water power, with directions for estimating the power of a stream, are given. Mills, from the largest to the smallest, are illustrated in full, with every accessory to their proper workings, including machines for cleaning the grain before grinding, to those for packing the finished flour, and in the minutest detail, showing every part, wheel, nut, screw, etc. But we can not enumerate the contents of this interesting work, suffice it to say that it shows every step, after the wheat leaves the threshing machine, and after the corn comes from the hands of the husker, needed to convert the one into flour and the other into meal. We were pleased to note that, while large establishments are provided for, the needs of small mills are not overlooked. One can procure a complete mill, with two run of stones, one for wheat and the other for corn, with every accessory, including motive power, ready to be set up in any one or two story building, as seen in the engraving, at a very moderate outlay. In

those wheat-growing localities, where the grain has to be sent a long distance to a mill, and the flour, for use, returned an equally long distance, a farmer, or several associated farmers, may easily establish such a mill, and it would no doubt be a

### Loading Logs.

A log is a heavy and difficult thing for one person to handle, unless he takes advantage of it. By *advantage* we mean, availing ourselves of any con-

LOADING LOGS ON TO A WAGON.

profitable investment, and at the same time a convenience as well as a blessing to the neighborhood.

### Ventilating Stables.

In the construction of stables there should always be a provision for proper ventilation, and at the same time for preventing any draught from falling directly upon the animals. While there is a wind, ventilation is easy to secure, but when the air is still, it is different, and the air of the stable too often becomes foul. The valvular window is generally preferred to all others for the introduction of air, and a plain ventilating shaft for carrying away the bad air. This ventilator, seen closed in figure 1, is a combination window and ventilator, the movable part being a sash of glass guarded by bars of iron. It is shown open in figure 2, the sash being against the outstanding frame. The distance to which the sash is opened is regulated by a ratcheted rod, fig. 3, fixed near the upper end of the ventilator. The air, as it enters the stable, must rise and pass in the direction of the arrows. The size of the ventilator should be about two feet square, and situated above the heads of the horses.

The foul air is best carried off by a small wooden shaft; passing from the top of the ceiling of the stable, to the roof, where it is protected by down-draught guards; one foot square is large enough for a stable of six horses. A section of a stable, with the shaft *a*, and ventilator window, *b*, shown in position, is given in fig. 4. It will be observed that the fresh air enters above the horses, and the foul vapors pass away above also, thus preventing any

Fig. 1.

Fig. 2.

chilling draughts that will surely come by having the air enter the bottom of the stable. There is a constant interchange of the upper and lower air.

trivance or mechanical power which enables us to avoid lifting it directly up by main force. In loading logs, the work may be greatly facilitated by using the inclined plane. In many places there is not sufficient snow for logging with sleds, and the wagon must be used. The engraving shows the method of loading logs upon a wagon by ox-power. Two strong skids, ten feet or so in length, are provided, one to be placed near each end of the wagon, as shown in the engraving. One hind wheel is then removed, the axle being blocked up; a chain is

Fig. 3.—THE RATCHET ROD.

fastened to the body of the wagon near the middle, and passing under the log midway from its ends, is brought back over the wagon to the oxen or horses upon the opposite side. With this arrangement the log is brought upon the wagon with very little effort. The team must be steady—and for this work oxen are to be preferred to horses—else the log may be carried too far, and all the work be lost. It is usually best to drag the logs into heaps, and, if possible, where the wagon may be on lower ground than the logs to be loaded. In snow, the same method may be used with a sled, with even greater ease than with the wagon, as it is lower.

### Tim Bunker on Town Bounties.

When I saw Seth Twiggs coming down Hookertown street with an uncommon cloud of smoke about his old beaver, I knew there was something in the wind. He hauled up at my wood pile, took a seat on a log, and said he:

"Did you ever see folks act so like a pack of fools as they did at town-meeting. Jest as we've got the foxes under a little, and pretty much scared 'em out of town, they must go and repeal the bounty. Why, I can remember arter the bounty was raised that we used to pay \$500 in town bounties on foxes, showing that we killed at least a hundred foxes every season. It wan't of much use to try to raise poultry, especially near any piece of woodland, for the foxes in spring would come right up to the barn and snap up geese, turkeys, and hens, even in the day time. Deacon Smith, I know, lost twenty dollars' worth of turkeys in one night, and I 'spose two thousand dollars would not pay for the poultry killed and carried off by the foxes. With hunting with hounds in the winter, and digging out the young ones in their holes in the spring, they had become mighty skase and poultry stood a good chance."

"I can tell jest what was at the bottom of the repeal," said Jake Frink. "Ye see, George Washington Tucker and myself took a scoot up thro' the

White Oaks last spring and holed an old she-fox' and arter digging the better part of a day, we took her out and six of her young ones, and got thirty-five dollars at the town treasury, bounty money, a pretty good day's work. Ye see this riled Uncle Jotham Sparrowgrass, Benjamin Franklin Jones, and a few more of their set, who had opposed raising of the bounty from two to five dollars. They said it was making money too fast and robbing the treasury. So they kept Hookertown street in an uproar all summer and talked agin bounties, until they made most folks thing it was the unpardonable sin. So you see when town-meeting was warned, it was put in to repeal the bounty on foxes. There was a general turn out at the meeting, especially of people who never owned a turkey or chicken, and the bounty was taken off. I guess they'll get their pay 'fore long in the price of chickens and turkeys."

This talk occurred three years ago last spring, and Jake's prophecy has come true. The repeal of the bounty has led to the multiplication of foxes beyond measure, and hardly a farmer in town has escaped visitation this summer. Poultry yards have been decimated, and in a few cases cleaned out, so that no Thanksgiving turkey is left for the spit. It has borne much harder upon the farmers back near the woodlands than upon people living on the street. The fox is a crafty creature, and loves his own safety, a little better than fresh turkey and goose. A farm-house near a bit of woodland is his special delight. He can steal a young turkey at any time and be out of sight before his theft is known. In the absence of bounties, there has been no special inducement to hunt foxes, our dogs have taken the place of hounds, and it is only as hunters have come in from the city that a fox has been killed. They have grown so bold that it is common to see them in the morning prowling around our barns. It is somewhat difficult to estimate the damage done by them, for they begin their depredations in the spring, killing geese and turkeys upon the nest, while sitting, or while yet with their broods, before the young ones are capable of taking care of themselves. Some farmers, who have sold three hundred dollars' worth of turkeys in a year, will not have half that amount this year. The tax upon the poultry yards is many times heavier than the bounty money would have been, and it is much

Fig. 4.—PLAN OF VENTILATOR OF STABLE.

more unevenly distributed. It is a mistaken policy to repeal the bounty upon foxes at any time. If it is kept on persistently, they will be hunted until they are driven from the borders of the town, and the bounty will be reduced to the minimum. Foxes are like weeds. None should be left to go to seed. They have fulfilled their mission, and no place should be left for them in a civilized State. They are unmitigated pests and too expensive to be tolerated. The policy of repealing bounties is pennywise and found foolish. If we try to save the bounties, the foxes will quadruple the amount by laying our poultry yards under toll. They will make poultry yards insecure and unprofitable. The true policy would be to have the bounties offered by the State instead of the towns. Then the ex-

termination would go on over a large territory at once, and if the policy were continuous, foxes would become as scarce as bears and wolves. There would be no unfairness in this mode of taxing, for the cities indirectly would be as much benefitted as the agricultural towns. Make poultry raising secure and its price is cheapened in all our cities.

Hookertown, Ct.,  
Nov. 5, 1879.

Yours to command,  
TIMOTHY BUNKER, Esq.

### Mines and Mining Terms.

The United States has the richest mineral deposits of any country in the world. The gold and

Fig. 1.—A BED BETWEEN STRATA OF ROCK.

silver mines are now yielding nearly 80 million dollars yearly, and the enormous deposits of silver ore and gold-bearing rocks discovered within the past two years, promise to double this yield whenever the new mines shall be opened and made productive. There were coined in the year ending June, 1879, over 65 million dollars of gold and silver, and these metals to the value of 12 millions were used in manufactures. The coal deposits are larger than those of any other country, each of several of the States having a larger area of coal than the whole of Europe, while the beds of the purest iron ore, and the veins of copper and copper ore, are equally superior in extent and value to any others in existence. The future development of our mining promises to surpass any thing previously known in the world. The recent wonderful discoveries of silver, and the rapid extension of mining, have created a general interest in mining, and the terms used by miners have passed into the periodical literature of the day. As every intelligent person, when reading of "levels," "slopes," "winzes," "bonanzas," and the like technical terms used in mining, wishes to know their meaning, we propose to give such a sketch of the general operation of a mine as will explain and illustrate them. Mineral deposits are found in the shape of beds or veins. A *bed* is a deposit lying conformable to and between the strata of rock in which it is found, as seen at figure 1, in which the dark, shaded part represents a bed. The immense deposits of silver bearing

Fig. 2.—A VEIN THROUGH BEDS OF ROCK.

lead ore recently discovered in the neighborhood of Leadville, Colorado, are in beds, and such beds are not of the regular or permanent character of what are known as true fissure veins. Veins differ from beds in penetrating the rock across the strata,

as seen at figure 2, in which the lines from *a* to *a* represent a vein cutting through the beds of rock, *g, g, g*. The point where the vein protrudes at the surface of the ground, is called the "out crop," and veins are most frequently discovered by finding its fragments, which are called "float," upon the sides of the mountain below the vein, or at the bottom. When these pieces of "float" are observed, the "prospector" searches above until he finds the vein from which they came. If the vein is a promising one, and is found to contain valuable mineral, a shaft is sunk to "prove" it. A "discovery shaft" is one sunk on the vein and following its direction for the purpose of proving its value. When this is found to be satisfactory, a working shaft is sunk perpendicularly through the rock in such a manner as to give the greatest facility in working the vein and raising the mineral to the surface. The shaft is shown at *b*, figure 2, and cuts the vein at some distance below the surface. A tunnel or "adit level," *c*, is driven horizontally through the rock to cut the vein as low down the mountain as possible, and through the vein to the main shaft to carry off water and ventilate it. From the adit level it is usual to sink other shafts, *d*, to reach the vein at a still lower level, and other "levels" are driven from the main shaft, as shown at *a, d*, to cut the vein in as many places as possible to make the working more effective and profitable. Veins are not regular in width or their direction; they "pinch" in places as at *e*, sometimes so closely that the "walls" are separated only by a mere thread of vein rock, while at other places the

Fig. 3.—HOUSE FOR THE SHAFT.

walls separate widely, enclosing enormous masses of mineral. When the ore found in such a wide space is rich, it is known as a "bonanza," and many millions of dollars of gold and silver have been taken from single mines in such places. The lower wall of a vein is called the "foot wall," and the upper one the "hanging wall." The wall is the surface of rock which is in contact with the vein, and is often smoothed and polished by the movement of the vein matter upon it pressing with enormous force. The rock outside of the vein is called the "country rock," and that in the vein, and with which the mineral is mingled, is called the "vein matter" or "gangue." This is usually quartz in fissure veins. When the shafts have been sunk and levels driven, the vein is said to be "opened on," and the work so far is known as exploring. The vein is then worked for profit. A house is built over the shaft for protection (*a*, fig. 3), and is called the shaft-house. Hoisting machinery is set up, and pumps are put down the shaft to free it from water. The work on the vein differs from that on the shafts. Figure 3 is supposed to represent the workings on a vein as would be seen if one side was exposed to view; the shaft is seen at *b*, the lines, *c*, are levels or "drifts," and the opening of these on the vein is called "drifting"; levels are usually driven at each 100 feet down the shaft after "pay-rock" is struck. At *d* is a "winze," which is an opening made perpendicularly from one level to another. At *e* the process of "stoping" is shown; this consists in taking down the vein matter from overhead, the rich mineral being taken

out and the waste being thrown down and left to fill up the level. At *f* is an "upraise," which is the reverse of a "winze," and is used to follow up

Fig. 4.—MINERS PASSING THROUGH THE SHAFT.

a deposit of ore richer than usual, and which, when it runs up into the vein, is called a "chimney." Such a deposit recently found in a California mine carried the market value of the stock from \$6 up to \$90 per share. The stoping on the vein goes on until all the valuable mineral is taken out, when the levels, as they are worked out, are abandoned. When the rock passed through, in a level, is loose and liable to fall, the level is timbered, as shown at figure 5. Very strong timbers are put together, as there shown, a few feet apart, and others are laid from one of these to the other when required to support the roof. An enormous quantity of timber is used in a large mine, and in some cases the timbering has taken fire from the lanterns or from blasts, and has burned out, doing much damage. It is in this way that mines take fire; and coal mines are sometimes thus fired, and the coal itself burns for months or years. At figure 4 are shown two miners descending a shaft on a tub, which is used to raise the rock and ore to the surface

**The Useful and Beautiful in Poultry.**—If we are to accept the statement of Darwin—and no one is more careful and reserved in his expres-

Fig. 5.—THE LEVEL TIMBERED.

sions than he—no domesticated animal admits of so much variation, beauty of shape, and richness in coloring, as poultry. But we are not called upon to accept this solely from the multitude of facts presented by this great naturalist in his work, "*Variation in Animals and Plants, Under Domestication*."

If one visits one or more of the many Poultry Exhibitions, now being held in widely separated parts of the Union, he will be convinced of its truth. There are breeds upon breeds, and varieties almost without number, some of them being quite new to the trade. To the making of new varieties of poultry, there seems to be no end; but with it all, the stock, as a whole, is getting better. Division of labor has come in, and some breeds are noted for their sitting powers, while others, so to speak, furnish the eggs, while others still, furnish the best flesh. It is pleasant to think that outward beauty, and inward usefulness, can be thoroughly combined in these birds; to know that in some cases, "fine feathers," do make "fine birds," and that a graceful form, and proud bearing, does not of necessity exclude solid and useful qualities.

### Training of a Kicking Horse.

A method of curing a kicking horse, or of training a colt to withstand any unusual pressure or contact of the harness behind, is described as follows: The animal is harnessed, as usual, to the shafts of a buggy or wagon; the shafts are then separated from the vehicle, being kept from trailing on the ground by straps or cords from the crupper,

DRIVING A KICKING HORSE.

as shown in the engraving. The horse or colt is then driven in the usual manner, the driver walking behind, and occasionally pushing the shafts to cause the breeching to press on the hind-quarters, or pulling them sidewise to interfere with the crupper, or in any way that may be possible, endeavoring to disturb the animal and train him to remain quiet under the disturbance. The horse may kick as he pleases, the shafts can not be hurt, as they are raised at every attempt. In time the horse will understand the matter, and refrain from kicking.

### The Sheep's Foot—Care and Neglect of It.

Foot-rot is a most destructive disease of the sheep. There is an incipient, and easily preventable, and curable form of this disease, and there is a malignant and contagious Foot-rot, which infects and poisons the soil, and spreads sometimes with most frightful effect, among large flocks, destroying the sheep by hundreds and thousands. The malignant form grows out of the other, and it is questionable if it could not be prevented from spreading among the sheep, even from infected ground, if their feet were only in good condition. But the sheep's foot is seldom in good condition naturally, because the

Fig. 1.

Fig. 2.

shepherd rarely thinks it necessary to examine it, until something wrong is evident, from the lame-

ness caused by it." Then precaution comes too late. The manner of growth of the sheep's foot is peculiar, and upon this depends its proclivity to damage

Fig. 3.

and disease. The walls of the hoof grow from above downwards, meeting the growth of the sole at the junction; the outer layers of the former being produced indefinitely, and if not worn away by contact with the ground, pass the sole and spread beyond it, turning under, and forming a loose covering, beneath which, moisture, filth, sand, stones, and other foreign matter find a lodgement. These foreign matters soften the horn of the sole, or otherwise injure it, so that disorganization, or destruction occurs, and carries the injury into the interior of the foot. Stones or gravel that may be enclosed under the excess of horn, press upon the softened sole and irritate the sensitive tissues under it, and although as yet, no actual damage may have occurred, yet the sheep is unable to walk upon its feet, and moves about on its knees. When this is seen, no time should be lost in examining the flock, and remedying the mischief, while this can yet be easily done. The feet will probably appear as shown at figure 2, the walls of the foot having out-grown the sole, and not only turning under at the sides, but turning up at the toes (figs. 2 and 3), thus preventing the natural use of the feet. This is to be remedied by the use of a pair of toe nippers, made expressly for trimming the feet, and also by the use of the knife. The walls of the feet are trimmed at the

sides with a knife, and all superfluous horn is removed. The toes are clipped with the nippers, figure 4; a pair of common pincers may be used, if the edges of the claws are filed and ground sharp. The hoofs then appear as at figure 5; the toes being clipped, to reduce the sole from the distorted form, to the rounded form, as shown at figure 3. Neglect of these precautions, has ruined many flocks, while the pastures have become so poisoned with the diseased and infectious matter, that no healthy sheep could be kept upon them, until after an interval sufficient to rid them of the contagion. The result of neglect may be described as follows: The horn of the sole being softened and decomposed, as previously mentioned, and the sensitive inner portions of the foot being injured, inflammatory and suppurative action is caused within the foot;

Fig. 4.—SHEEP'S TOE NIPPERS.

escape of the products of inflammation being impossible through the sole at first; intense suffering results, and a generally disturbed condition of the animal ensues. This is the first stage of malignant foot-rot. In course of time the sole is decomposed, and fetid pus escapes, by which the herbage and soil are infected. The disease spreads through the whole foot, and appears at the coronet. Fungoid, or mushroom-like excrescences appear on the sole, and at the coronet, and if neglected at this stage, the whole foot may be lost and the sheep ruined. In this condition, radical treatment is needed. The sound animals should be removed at once to new and clean pastures, or into a clean yard. The diseased sheep are to be treated, by means of cau-

tic dressings of the feet; Hydrochloric (Muriatic) Acid, diluted with three times its bulk of water; a solution of one dram of Chloride of Zinc, in a pint of water, or Carbolic Acid should be used to destroy the diseased growths, and persevered in, until sound parts are reached, when the usual stimulant dressings may be substituted. The sheep

Fig. 5.

Fig. 6.

should be kept on a clean floor, covered, or well dusted with fine air-slacked lime, or in a dry, clean, soft pasture, which should be plowed, so soon as its use by the sheep is no longer necessary.

### The Boys at Work.

#### Interesting Experiments in Corn Raising by 138 Maine Boys.—An Example Worthy of Wide Imitation.

Stillman B. Allen, Esq., for many years past in successful business in Boston, retains a lively interest in the place where he spent his boyhood, a quarter of a century or more ago—York County, Me. One of the ways of manifesting this interest is in stimulating the boys of the present day to observation, thought, and experiment. Last spring he offered \$200 in seven prizes—one of \$100, one of \$50, and five of \$10 each—to the boys in the County under 17 years of age, who should produce the most Indian corn upon one-eighth of an acre. Each boy intending to compete was to send his name before May 1st, to the President of the County Agricultural Society, who had charge of awarding the prizes. About 200 boys reported. A committee of one or more men was appointed in each town to measure every parcel of ground, and to be present at the harvesting, husking, and weighing of the crop, and report at the Town House in Alfred on Oct. 25. Each boy was required to fill out the blanks furnished, giving a full account of the time of plowing, planting, kind of seed corn, and full particulars as to manure, cultivation, etc. (These blanks will be bound in book form by Mr. Allen, and kept in the archives of the County Agricultural Society for reference and use.) We have before us the report of Mr. John Hall, President of the Society, giving a full account of the results obtained by 138 of the boys, some 75 of whom were present with their parents and many others, at the time of making the reports. We regret not to have been among the number to have seen the displays of the specimens of corn, and especially to have seen the bright-eyed, enterprising boys. We have space for but an epitome of some of the results. The ears were reckoned at 70 lbs. for a shelled bushel of 56 lbs.

The average yield of the whole 138 trials was just about 100 bushels of shelled corn per acre. The first prize was awarded to Moses Milliken, of Biddeford, for 160 bushels per acre. 2d to David J. Morrell, of Cornish, 153 bushels. The next five prizes went to A. O. Bennett, of Waterboro, 145 bushels; Cyrus H. Smith, of Dayton, 144 bushels; Willie B. Moore, of Limerick, 142 bushels; Charlie G. Austin, of Lebanon, 141 bushels; and Arthur M. Deering, of Waterboro, 140 bushels. Six boys raised 131 to 137 bushels per acre; 12 raised 120 to 127 bushels; 23 produced 110 to 119 bushels; 24 produced 100 to 109 bushels—making 72 boys who grew 100 bushels and upward. 22 others produced from 90 to 99 bushels per acre. 29 obtained 75 to 89 bushels, and only 15 fell below 75 bushels of shelled corn per acre. Doubtless, owing to poor soil, lack of fertilizers, etc., many of the boys getting the lesser crops were entitled to high praise for their efforts. Indeed we commend every boy who had the intelligence and spirit to enter the contest.

This shows what can be done in producing corn in a county in Maine, lying between 43° and 44° of

north latitude. Not having the reports before us, we can not judge as to the profit of such crops, the cost of manure, cultivation, etc., nor are we concerned as to this in the present case. The important result is the effect upon the boys themselves, and upon many other boys in the county and elsewhere. These boys were led to *think, reason, observe*. They will each examine into how and why this and that one succeeded better or poorer than themselves. They will be better thinkers and workers hereafter. Mr. Allen's thoughtful offer will be worth to his native county, in the far reaching future results, more than tens of thousands of dollars expended in some ways that might have been selected. We heartily wish there might be a Stillman Allen for every county in the whole country; and where there is not, we suggest that a

Fig. 1.—WINTER WATER TROUGH.

like sum—if necessary one of the \$200 prizes often given to some fast "nag"—he appropriated by the Society to the benefit of some hundreds of youth. The boys of "17 and under" of to-day, are to be the actors upon the stage a very few years hence.

P.S.—Mr. Allen is so pleased with the result in York County that he now offers prizes of \$200, \$50, and five prizes of \$10 to the boys of the entire State, who shall produce the most corn from one-eighth acre during 1880. Those not over 18 years, who desire to compete, will send their name and address to Hon. B. F. Hamilton, President Maine State Agricultural Society, at Biddeford, Me.

### Hints and Helps For Farmers.

**A WATER TROUGH FOR WINTER.**—An ice-clad water trough for cows to drink from is neither pleasant to them nor profitable for their owner. To raise 20 or 30 quarts of water from freezing point to nearly 100 degrees, will use up the effect of a large quantity of food, which should be made to do more useful work. In such cases the waste of food and loss of vital force, and consequently of fat, flesh, or milk, is very large, and is one of the largest leaks of the farm. Water coming from a well or spring at a temperature of 50° to 55°, and drunk at this temperature will not chill an animal, but refresh and invigorate it. But if the water is not freshly drawn, and the trough is covered with ice, it chills the animals thoroughly, and they will not drink as much as they need. A water trough that may be kept free from ice and snow is shown in the engraving.

Fig. 1.

Fig. 2.

It is suspended on pins at the ends, fitted in posts as shown in figure 1. When not in use, it may be turned over and kept free from snow, and as the trough is empty, no ice can form in it. For the purpose of turning it over easily a handle, *a*, is fixed to one end, and when not in use is fastened to the

fence by a wire loop or a hook, thus easily preventing the trough from being inverted by accident.

A BAG HOLDER that may be made and applied in

Fig. 4.—WAGON JACK.

a few minutes is shown at figures 2 and 3. Figure 2 represents two pieces of wood joined, and suspended by a cord or light rope, as made plain by the engraving. At figure 3 is a bag held open by the holder and suspended by the cord. By the use of this simple contrivance, one person can, without help, fill a bag in the easiest manner.

**WAGON JACKS.**—Clarence Hollins, Todd Co., Ky., sends a sketch and description of still another Jack, which is shown in figure 4. The piece, *A*, is made of oak or other strong wood, and should be five feet long, six inches wide, and two inches in thickness. The cross-bar, *B*, is to keep the jack upright. The portion *C*, is 26 in. high; *E*, *E*, are pins to keep the lever, *D*, down. This Jack is easily understood. The engraving tells the whole story.

WAGON JACK No. 2 comes from S. P. Harrington,

Fig. 5.—WAGON JACK NO. 2.

Marion Co., Ind., who has used it for 12 years, and finds it in every way satisfactory. Its construction is simple: Take a piece of hard-wood 1½ in. thick and 2½ in. wide, 5 feet long; another piece of the same size 2 ft. 8 in. long is fastened to the long one, near its middle, by a bolt. In using the Jack take hold of the long piece, and putting it under the axle at one of the notches, raise the wheel, when the short piece follows it up and holds it in place. When the wheel is to be lowered, the lever is raised a little, the short piece is pushed back with the foot, and the work is done. The jack appears to be handy, and is certainly easily made and cheap.

### Barn-door Fastenings.

A number of years ago, the writer had a colt that was uncommonly crafty, and soon became an expert in opening barn and stable doors. The door to the horse-stable, was fastened by a sliding wooden bar (fig. 1), moved by an out-standing pin; this door was easily opened by the colt, until a hickory spring was put on the bolt, which kept it firmly in place. A contrivance like this, makes the fastening a self-acting one, when the door is swung closed. The door to the adjoining barn, opened by a latch string, (fig. 2), and this the rogue found, and could grasp with his teeth, and pull down, when the door would open. For a time we pushed the strap through the hole, but this, though it kept the colt out, made it difficult for us to open it. We soon thought of putting a strip of board—a sort of awning—over the strap, as shown in figure 3, and this proved effectual in preventing the colt's proceedings. Any further efforts of his were unavailing. The old hand-hole and hook fastening, is one that is very safe, and quite convenient. As shown in figure 4, it consists of an iron hook, attached near the inner edge of the door, and is

Fig. 1.

hooked to the casing by the hand, which passes through the hole, when hooked from the out-side. There may be an objection to this method of fastening, because it leaves an opening for wind to pass in. This may be remedied by tacking a piece of leather over the hand-hole, leaving the bottom unfastened.

### Fodder Plants—"Teosinte."

At no former period has there been so much interest felt by our farmers in plants producing green fodder, as during the past two or three years. This interest is wide spread, and extends not only north and south, but, as our correspondence shows, from Nova Scotia to Washington Territory. This is a gratifying feature in the present condition of our agriculture, as it shows a disposition to get out of old ruts, and to ascertain if there is really anything better than we now have, and also indicates that soiling, regarded by the best dairymen as the best

Fig. 2.

practice, is receiving a more extended trial than heretofore. Among the present green-fodder plants, Indian Corn stands at the head. But fodder-corn covers only a part of the season, and yields but one cutting, while there is a desire for earlier plants, and those which will bear repeated cuttings, and give a succession of succulent food, thus getting a much larger return from the same area of ground. Besides, there are some who do not think that fodder-corn is the best food for furnishing the best butter; not so much that it imparts an unpleasant flavor to the butter, as that it fails to give the butter that peculiar aroma that comes from the best pasturage. But those who have tried Indian Corn as a green fodder, find it to possess so many advantages, that they are not likely to abandon it, until something decidedly better is brought to their knowledge, and they have tested its value. Is there anything that is, on the whole, better?—We are not prepared to answer this question; but with a view of reaching an answer, we have, in the past two or three years, brought to notice, figured and described, the various new plants—or new to use—as they have come to our knowledge, giving such statements in regard to them as were to be procured. We have had the various kinds of Durra, Guinea-grass, Prickly Comfrey, Pearl Millet, and others, each one of which has shown its value in some localities. That we shall find another plant that will be so generally and widely valuable as Indian Corn is not to be expected. Nor is it to be expected that a plant that will give five or six cuttings in the season in the Cotton States, will be equally productive in Maine. Still, take the trials that have been made, the country through, they have been on the whole useful, and the more so, perhaps, the farther south they

Fig. 3.

Fig. 4.

have been made. Among the various new plants is one we have not yet noticed, "Teosinte"; though the seeds of it were offered last spring by Mr. Carson, there was but little to be learned about it. The seeds have been sent from the Royal Gardens, at Kew, England, to various British Colonies, including the Bahamas and the West Indies generally, Cyprus, South and Tropical Africa, and Australia. The reports from most of these localities, and others, have been favorable, almost to extravagance. Sir Joseph Hooker, the Curator of Kew, kindly sent us a packet of the seeds, and a trial showed us that while the plant can hardly be of great value in northern localities, it is evidently of wonderful promise for the Southern States. The recently re-

ceived Report of Kew Gardens has figures of the plant, which came to perfection at Kew, under glass.

The luxuriance of the plant, even with us, is something remarkable. A single seed produced 12 or more stalks, very leafy, and of a dark green, and a rankness of growth, indicating that it would like to have a hot and long season, just to show what it could do if it had a chance. Our plants were but

thing enormous. Caution.—Observe that what we have said applies to the plant in tropical and sub-tropical climates, and we doubt that it will be valuable north of Virginia, if even so far north as that.

### Cut-Leaved Trees—Paper-Mulberry.

Among the variations from the usual form, of which our ornamental trees and shrubs are capable, none are more popular than those called "Cut-leaved," and sometimes "Fern-leaved." On most trees and shrubs, the leaves consist, as may be easily seen, of a frame-work of fibres, the spaces between which are filled up with a, usually, dark green pulpy matter. This soft substance is the part removed in making "skeleton leaves." The fibres of leaves, when large, are called "ribs," and these, in most leaves, are arranged on two principal plans. A main rib starts from the base of the leaf, where that joins the foot-stalk or petiole, or if there be no petiole, where it joins the stem, and runs directly through, to the point, dividing the leaf into two, more or less, equal parts. From this, which is called the "mid-rib," start smaller fibres, or veins, and run more or less directly towards the margin. In other leaves there is no mid-rib, but there are three, five, or more strong ribs, starting from the base to the circumference. The first class of leaves are called *pinnately-veined* (like a feather), and the other *palmately*, (like the hand with out-spread fingers), or *radiately-veined*. In the first case, the leaf is usually longer than broad, while in the radiately-veined-leaf, its shape will be more or less rounded in form,

like the leaf of the Maple. In some leaves, the margin is entire, but as is well-known, they present every variety of division, from a mere notching of the margin, to those where the divisions extend far

as it is its natural form, but when the leaflets themselves become divided, it is then the "Cut-leaved," or "Fern-leaved" Sumach, and one of the most beautiful shrubs in existence. These unusual forms of leaves are due, so to speak, to a deficiency of their green or pulpy portion: there is not sufficient to fill up the spaces between the frame-work, and what there is, clings to the ribs or veins, leaving open spaces between. Hence the "cutting" will follow the direction of the fibrous framework of the leaf, and the much "cut," pinnately-veined leaf, will produce a very different form from the radiately-veined one. It is in the detecting and propagating such unusual forms as cut-leaved trees and shrubs, that the horticulturist finds one of his chief pleasures. So far as we know, there is no method by which these interesting, and often elegant forms, may be produced at will. They are usually mani-

Fig. 1.—"TEOSINTE" (*Euchlaena luxurians*.)

five or six feet high, while it reaches, when fully developed, 12 feet or more. The plant was first introduced as *Reana luxurians*, but according to Hooker, its proper name is *Euchlaena luxurians*; its specific name is descriptive, as it would be difficult to find a plant of a more luxuriant appearance. To the botanist the *Euchlaena* is of great interest; it is a near relative of Maize, producing, like that, its staminate flowers in a "tassel" at the top of the plant, as shown in figure 1, taken from the plant at Kew. It also, like corn, has its pistillate flowers at the nodes—or joints below, inclosed in a leafy involucre, or "husk." But there the close resemblance ends. In the corn, the pistillate flowers and seeds are in many rows upon a short branch (or cob), in this they are closely placed in rows upon slender branches or spikes, one of which is shown at the upper left hand, in figure 2; which gives the appearance of the "ear," within which is inclosed a number of such small spikes. We can only say that the reports made to Kew from several hot countries to which seeds had been sent, are such as to warrant a thorough trial of the "Teosinte" in our Southern States. Dr. Sanders, in Madras, put in the seeds at five feet apart; soon the plants so spread that they all touched, the produce of some single seeds being 100 to 120 stalks, and suggests that it would be a valuable fodder for elephants! The report from Australia states that it withstands the severest drouths. Being a perennial, it will allow of repeated cuttings, and we judge that the amount of fodder that an acre of "Teosinte" will produce in a favorite climate is some-

Fig. 2.—THE "EAR" AND SPIKE.

festated by the young seedling—"Congenital deformity" we should call it in an animal, and kill the young creature at its birth; but in the plant, we cherish and propagate it. Some trees when they first start from the seed, or when they push up a vigorous shoot from a stump, after the tree has been cut down, produce leaves, unlike those of the mature growth. The *Pinus*, *Catalpa*, and others, produce on young shoots, leaves of enormous size. The common Paper-Mulberry, (*Broussonetia papyrifera*), under such conditions, has not only

unusually large leaves, but those singularly and often grotesquely lobed and cut; but these peculiarities disappear after the stem is a year or so old, and may be regarded as a condition of infancy. But a variety of this tree has been raised in France, from seed, by M. Billard, which is, to judge from the figures published in *Revue Horticole*, one of the most striking of all cut-leaved trees. In the engraving here reproduced from the above named journal, are shown two of the leaves, which it will be seen are little more than skeletons. In the normal form, the leaf is somewhat heart-shaped, with three strong

THE CUT-LEAVED PAPER-MULBERRY (*Broussonetia papyrifera*, var. *Billardi*).

into the substance of the leaf. Examples of trees, which have leaves much divided in their ordinary condition are not rare, but these are not included under the term "cut-leaved," that term is applied to departures from the normal form. The ordinary Sumach has its long leaves, divided into many (11 to 30) leaflets, but we do not call this "cut-leaved,"

radiate veins from the base. In this variety, all the pulpy portion is gone, save a very small quantity at the ends of each of the three veins. Evidently there was not material enough to carry out the plan of the leaf. This variety is named var. *Billardi*, and has not, so far as we are aware, yet been offered for sale by the nurserymen of this country

### The Two-Colored Bush-Clover.

The great value of hardy late blooming plants in our climate has rarely been so strikingly manifested as it was last autumn. Two or three sharp frosts took away the very tender things, after which the hardy late bloomers had it all their own way for some weeks. The Two-colored Bush-Clover which

blooming plants. This *Lespedeza* is given in the European journals and horticultural works as a shrub; it is shrub-like in habit, but not in duration. The stems, though quite strong and woody, die down nearly or quite to the ground at the end of the season, new ones appearing the next spring, and growing rapidly. It is really a herbaceous perennial rather than a shrub, and as would be

especially suited to our summers, are the Tuberous-Rooted Begonias, especially the hybrids. The genus *Begonia* is a very large one, and its numerous species, natives mostly of South America and tropical Asia, present such a diversity, that there are several distinct groups. One section, of which *Begonia Rex* is an example, has very short stems and insignificant flowers, but most beautiful leaves, and

THE TWO-COLORED BUSH-CLOVER (*Lespedeza bicolor*).

has been for some years a favorite with us, showed how well it deserved our partiality by holding out to the very last, and bloomed until checked by exhaustion rather than stopped by the cold. The title given above is a translation of its botanical name *Lespedeza bicolor*. The genus *Lespedeza*, so named in honor of Lespedez, one of the Spanish governors of Florida, is one of the large Pea Family (*Leguminosæ*); its neat three-parted leaves and very small flowers (though not in close heads) are enough like those of clover to warrant the common name of Bush-Clover. There are several species found in most parts of this country, but as none are very showy they rarely attract the attention of any but botanists. The species in question, *L. bicolor*, comes from the region of the Amoor river in Northern Asia. It forms a much branching half shrubby plant from three to five feet high; its branches being long and slender, droop at their extremities, giving the mass a most graceful appearance; the stems and foliage are of a very pale green, being covered, at least when young, with light silky hairs. The flowers, shown of the real size in the engraving, are in sufficient numbers to compensate for their small size, as they quite clothe the branches. In color they are of a delicate tint of rose, which may be described as violet rose. The general effect of the plant, the modest flowers combined with, rather than contrasted with, the subdued color of the leaves, is most pleasing. Not the least of its good qualities is its long endurance; beginning in August, it remains in flower until the time of killing frosts, and is a capital addition to our late-

inferred from its far northern origin, is perfectly hardy. It is not particular about soil, and is easily multiplied by cuttings. We received this plant as *Desmodium penduliflorum*, and there seems to be much confusion between the two, *Desmodium* and *Lespedeza*, in European collections.

### The Tuberous-Rooted Begonias.

While planting in bedding designs, or as the French call it, "Mosaic planting," with Coleuses and other plants with colored foliage has been successfully done in this country, the attempts to produce similar effects with flowers have rarely been satisfactory. This general failure is due to following English examples. Excellent designs, with the plants to be used in carrying them out, have been given in the English journals, but an attempt to reproduce these with the same materials, in this country, have been mostly miserable failures. The difference in the climate of the two countries will account for this. Plants that in the moist climate of England will bloom all summer, with us have a very short flowering season and are done with. For garden decoration of this kind, the working out of designs with flowers, we must find a very different set of plants from those used abroad. While our hot summers make most of the plants used for this work in England, unavailable with us, we, on the other hand, can employ those which the English gardener would not think of putting in the open ground. Among the plants with brilliant flowers,

TUBEROUS-ROOTED BEGONIAS.

are solely cultivated for the ornamental character of their foliage. Another set, represented by the beautiful *B. hybrida multiflora*, are profuse bloomers and are among the most popular winter flowering plants. Not many years ago there were introduced several species different from others in habit, in producing a large tuber at the base of the stem; these, their flowering season being over, stopped growth, dying down to the tuber, which, after a season of rest, was started anew. *B. Bolivienensis*, *B. Vietchi*, and *B. Froeheli*, and others, are South American species of this group. Soon after the Tuberous-Rooted species came into cultivation, it was found that they hybridized with the greatest ease, and that the resulting hybrids often excelled the original species in the size and brilliant coloring of their flowers; they are now among the most popular plants abroad, and are rapidly coming into favor as they are better known in this country. The plants have generally a good habit, grow from one to two feet high, and produce the greatest profusion of flowers, differing widely in size and shape, and presenting a wide range of colors, which are clear and well defined, and often remarkably brilliant. The engraving, made up of a collection from a number of these new hybrids, shows all that a wood-cut can give, the shape and relative size of the flowers, and whether they are dark or light; the brilliancy in some, and the delicate tinting in others, we can not give; they are given here at about half their real size, and are of every shade, from pure white through the most delicate rose and pink to the deepest shades of crimson and scarlet,

and on the other hand from the most delicate cream and sulphur colors up to the deepest orange. In many the leaves are very elegant, not only in form, but they are often handsomely veined and tinted. The catalogues of the European dealers offer about a hundred named varieties, and though the lists of our florists are not so full, they offer a good selection at moderate prices. Not the least of the merits of the Tuberous Begonias is the ease with which they are raised, and if one can get seeds of a good strain, plants quite as fine as the named varieties may be produced. A pot of good, rich, light soil should be prepared; the very fine seeds are to be sprinkled over the surface, and merely pressed down into the soil; cover the top of the pot with a pane of glass, and keep in a temperature of 50° to 60°. When the plants are large enough to handle, pot them off into similar soil. Started in February, and well cared for, the plants will be large enough to turn into the open ground and flower the same summer. They may be kept in pots to bloom in the greenhouse, for the decorating of which in summer they are especially valuable. They are essentially summer-bloomers, and when their bloom diminishes the water should be gradually withheld, the tops allowed to die down, and the tubers allowed to ripen; these may be kept in the earth, or taken out and preserved in a warm place until spring, when they are to be potted and started into new growth.

### What is the Black Knot?

The conspicuous excrescence often found upon Plum, and wild, and cultivated Cherry trees, and well named the *Black Knot*, is an old enemy to the fruit-grower. From its destructive nature it early received the attention of scientific men, and much has been written and said upon this subject, in fact, much more than was really known. Some have claimed that the knot was caused by insect stings, a form of gall, in nature like those on the

Fig. 1.—MATURE STATE.

oak, willow, etc. The fact that the knots—especially the old ones—frequently contain insects and their eggs, remains, etc., was accepted as evidence that such was the case. Though many investigators have found a fungus present in the knot; it having been first described by Schweinitz, in 1838, yet, until the recent, and thorough investigations made by Professor Farlow of Harvard University, all doubt of fungus origin was not cleared away. The following are his reasons for believing that the knot is not caused by insects: "First the knots do not resemble the galls made by any known insects. Secondly, although insects, or remains of insects are generally found in old knots, in most cases, no insects at all are found in them when young. Thirdly, the insects that have been found by entomologists in the knots, are not all of one species, but of several different species, which are also found on trees that are never affected by the knot. On the other hand, we never have the Black Knot, without the *Sphaeria*

*morbosa*, [The scientific name of the fungus. Ed.]... and the mycelium of that fungus, is found in the slightly swollen stem, long before anything that

Fig. 2.—YOUNG STATE OF THE BLACK KNOT.

could be called a knot, has made its appearance on the branch; and furthermore, is not known to occur anywhere except in connection with the knots."

The Black Knot is most conspicuous in the winter season, when the trees are not covered with foliage, and they range in size, from half an

Fig. 3.

Fig. 4.

inch, to a foot or so in length. The knot does not usually surround the branch on all sides, but growing from one side, often causes the branch to bend away from that side, or twist into an irregular shape. A knot, much reduced in size, is shown in figure 1, with its surface undulating, and more or less cracked. When the knot is a large one, it usually kills the branch, or continues to spread up and down from the old knot, until death comes to the branch. Figure 2 shows the Knot in its early stages. In the spring the affected part increases rapidly in size—one might almost say puffs out—and the whole, growing larger, becomes thick and is soft; rupture of the bark soon follows, and the soft substance, coming to the surface, expands rapidly, and is soon coated with a characteristic greenish color. All this time the threads of the fungus have been increasing rapidly; in fact, the swollen substance is made up largely of these threads, and as they develop and become exposed by the rupture of the bark, multitudes of spores form on the interior filaments. Figure 3 shows a thin section or slice through the young knot, with the exterior threads of the

Fig. 5.—SECTION OF PIT.

fungus, producing small spores, *a, a*. The same is seen more highly magnified in figure 4. This takes

place about the time the cherry and plum trees are in flower. These spores continue to be formed, until midsummer, when a new development begins, which is for the production of the winter spores. As autumn approaches, the black color develops, the outer surface hardens, and frequently the interior soft substance is destroyed by insects, and only a shell remains. In this crust, are small nodules, or protuberances, one of which is shown in figure 5. These nodules are pits, on the inside of which a multitude of small sacs are attached.

Figure 6 shows two of these sacs, in each of which are eight spores, the universal number in this species of fungus. These spores are not fully developed, until very late in the season. The Choke Cherry (*Prunus Virginiana*) is a favorite home for the Black Knot, as the neglected fence rows in winter show. Next to the choke cherry, in the severity of its attacks, are the cultivated varieties of cherries and plums.

Fig. 6.—SPORE SACS.

"The Morello Cherry is more susceptible than any other variety, and next in order comes the Mazzard." Some varieties are free from the knot.

REMEDY.—Like all troubles caused by fungi, the Black Knot is contagious, and is propagated by the millions of spores it produces, one crop of which is developed through the spring and summer, and the other in the late autumn. The knife is the remedy. Cut off the knots, wherever, and whenever found, and burn them. This can best be done in autumn, after the leaves have fallen, and the knots are exposed to view. The Choke Cherry hedges and trees, might better be cleared away entirely, if situated near pear or cherry orchards.

### How the Japanese Pack Bulbs.

Travellers in Japan, give interesting accounts of the gardens of that country, and tell of the ingen-

JAPANESE LILY-BULB CASE.

ious appliances, such as shades made of bamboo strips, and greenhouses covered with paper, so prepared as to serve as a substitute for glass. The specimens that come to us, show that they are well advanced in the art of horticulture. We saw the first of the beautiful Japanese Maples that came to this country, and these, as well as other plants, showed, that in grafting, they had little to learn from us. We were recently at the opening of a case of lily bulbs, just imported, and these were packed in a manner that showed not only great care, but a knowledge of the requirements of the bulbs. The bulbs in question were remarkably fine ones, of the golden-handed lily, *Lilium auratum*. Upon opening the case, only large flattened balls of dried mud were to be seen. Each bulb was enveloped by a covering of what appeared to be dried

swamp muck. The bulbs had each been thoroughly covered when the earth was moist and plastic; this was worked around the bulb by the hand, to fill all the interstices among the scales, then well formed and smoothed, and afterwards dried. When this covering was removed, the perfect condition of the bulb showed that the Japanese well understood what was required for their safe transportation. The engraving shows the appearance of the bulb, with a portion of its covering removed.

### Woodchucks in the Garden.

The woodchuck, (*Arctomys Monax*), is one of the most troublesome pests of the farm and garden. Though exceedingly shy, he not infrequently prepares his burrow in some corner of the garden. His favorite food, in the meadow, is clover, and the amount of this food a community of woodchucks will destroy, is enormous. In the garden, his favorite food is lettuce, cabbage, and beans. His presence is generally indicated in the early spring, by the mysterious disappearance of the leaves of young cabbage, just transplanted, so that the gardener is in doubt for a time, whether the woodchuck, or the worms have been foraging. A little watching at noon, or just at evening, from a safe distance, generally reveals the intruder with head erect, on the lookout for his enemies. There is no safety for anything in the garden, while this pest is abroad. The mouth of his burrow is usually in a bank, or side-hill, or stone-wall, has many apartments, and several openings, so that it is almost impossible to drown him, or smoke him out. It is not easy to trap him, and his ear is so quick to catch the slightest sound, that it is difficult to get near enough to shoot him. Having suffered much from these visitors in years past, we determined, this season, to try a new remedy. Noticing that the young cabbage disappeared regularly every day, we transplanted a large cabbage, with leaves six or eight inches long, in his favorite feeding ground. The leaves were dusted over with Paris Green. The second day after the transplanting, the most of the heads disappeared. The third day, we found near the mouth of the burrow, a large female woodchuck dead. We continued the experiment for a few days about the mouths of the burrow, and the depredations entirely ceased. This is altogether the cheapest, and surest method of destroying the pests, that we have ever tried. Paris Green is in almost universal use for destroying potato bugs, and every farmer can avail himself of this remedy, with very little trouble. Of course the same precautions are to be used in poisoning woodchucks, as potato bugs. A dime expended in Paris Green, will save many dollars worth of vegetables. CONNECTICUT.

### The Plant Individual.

When we look at one of the higher animals, it is evident that we see an individual—a single unit of the kind—a whole not capable of living in a divided state. We get our idea of an individual from such forms of life because here it is the most distinct and therefore evident. As we descend in the scale of animal life, the evidence of individuality diminishes, until we come to forms where it is entirely swallowed up, and only communities or congregations of individuals are seen. For example, in the coral we find a number of units joined together through life. Among plants the individual is still more difficult to observe, and is a point upon which there has been considerable discussion. Some have held, that all which comes from a single seed is an individual. This would make some units very large indeed. All plants not propagated by seed, as the various varieties of apples, pears, potatoes, etc., etc., according to this view, would consist of single individuals. All Baldwin apple-trees would belong to the same individual. This limit for the plant unit is too broad, and will not answer. Another, and the generally accepted, view is that a plant individual consists of the smallest part which in general will live and grow when separated from its former place and given fitting conditions for growth by itself. The gardener, in making a cutting of a

geranium or verbena, for example, takes a portion of the stem containing a bud—it may be very small—and places it in the sand. A man in grafting, fastens a similar portion of one kind of plant in another. Such a portion is now considered the plant individual. In this light a tree or shrub is not a plant unit, but rather a single plant community in which the individuals are united in a common work, and in great measure dependent on each other, because a division of labor is maintained.

We speak of a maple tree as an individual, but it is so only, as a swarm of bees is a unit of life; in fact, we can find considerable similarity between the tree and the hive. The bulk of the plant is made up of the ordinary foliar units, which have no sexual organs developed, and are for the elaboration, formation, gathering so to speak, of the nourishment of the whole community—the plant hive—they are the *workers*, and *neuters*. Other individuals are devoted to the work of producing new colonies, namely, the stamens in the flowers, which perish as soon as their work of fertilizing the pistils is accomplished; these are the *drones*. The *queen* of the plant hive is the pistil, in which seeds develop, and when mature, are ready to separate from the parent, and form a new and independent plant colony. A large growing tree is a vast and constantly increasing community of plant units, each consisting of a bud and a portion of the stem which bears it.

### Impeachment of the Robin.

The robin (*Turdus migratorius*) is the favorite bird of the Northern States, coming early in the spring, and leaving only with the killing frosts of autumn. He is not infrequently seen in mid-winter, in mild seasons, amid the boughs of red cedar, or other evergreens in sheltered places. We hardly know the secret of his popularity; for he is not more beautiful than many other birds, has no sweeter song, is no more useful, but the greatest pest. We are sorry to disturb the confidence of cultivators in this favorite bird, but after the observation of several years, we are obliged to put him down among the pests of the garden. Last spring a flock of robins settled in the vicinity of my garden. Their first depredations were upon the strawberry bed, where they gorged themselves with luscious Monarch of the West, and picked and marred more than they ate, until I invested in an old fish seine, which covered the bed. As the green peas swelled in the pod and became large enough for a side dish with roast lamb, they tore open the pods, and scooped the contents. I admired their taste, but was vexed at the daily thefts. When the cherries turned red they perched in the tree tops and sung their songs as gaily as if they never looked at the cherries below. They devoured peeks of them and never said a word about the theft. When the currants ripened the robins seemed to invite all their neighbors to the feast, probably because I had fought currant worms for three years, and had a good crop, while my neighbor's bushes had been killed by these insects. The birds took the better half of my crop. I thought there might be some rest after the small fruits were gone. But when the Beurre Giffard pears ripened in early August, the robins punctured every red cheek, selecting the handsomest fruit, with the eye of an epicure. They followed the pears steadily for three months, living upon the fat of the land, and only spared the winter pears because they were too hard for their taste. They visited the grape trellises as soon as the fruit was ripe and followed them until frost came. What have I in return for this wholesale depredation? Absolutely nothing which I cannot get cheaper elsewhere. Insects destroyed, you suggest? Not much. They did not clean my currant bushes of worms. Hellebore did that. They did not clean my apple, cherry and elm trees of canker worms. Tar did that, effectually. Well, they sung, you say. Yes, but I have better and cheaper music in the house. I see no good reason why this pest should be spared and cultivated. So next season when it is inquired: Who killed Cock Robin? the answer will not be "I, said the Sparrow, with my bow and arrow," but "I, Connecticut's son, with my two-barreled shot-gun."

## THE HOUSEHOLD.

For other Household Items see "Basket" pages.

### Holder for Wisp Broom.

A design for making a handy and useful article is here given. It is a holder for the wisp, or short-handled broom-corn clothes brush, so generally in use. The holder is cut from Bristol board; it may be all in one piece, and folded in the middle, or of two similar pieces, each forming a side, with their edges fastened together with ribbons or any other way that fancy may suggest. It is then hung

Fig. 1.—HANGING WISP BROOM-HOLDER.

for use by two or four strings. In figure 1 is shown the appearance, as regards general shape, etc., when complete. It will be seen that the holder is open at the top and bottom, and that the brush is put in at the top, handle down, and when desired it is drawn out through the bottom. The side may be ornamented as one may fancy. We saw some at a recent fair, with the injunction, "Brush your clothes," wrought in letters and curves upon the side. But this is rather superfluous, and suggests that the person addressed is not neat in his habits. We see no reason why the holder could not be fastened to the wall by one side, and thus do away with the strings. A case for carrying the broom when travelling is shown in the second engraving. Those who are puzzled what little present they can make for a friend, who is going away, have here a

Fig. 2.—TRAVELLING BROOM-HOLDER.

very simple thing, easily made, and which will be in daily use. It is merely two pieces of paste-board of the same size, fastened together by pasting strips of cloth over their long edges. It is then to be papered neatly, and trimmed as one fancies. It may be ornamented by cutting initials from paper of another color and pasting them on, or these may be put on with water-colors. The size will be ac-

cording to that of the brush, which should be so compressed as to occupy about half its former width. If preferred, the covering may be of embroidery or crochet-work, as the ornamentation may be carried out in considerable variety.

### Cleaning Chimneys.

Foul chimneys are at this season a source of great danger; soot is very inflammable, a mere spark will set it on fire. No one knows the condition of his chimneys, what cracks there may be in the brickwork, nor what timbers there may be near those openings through which fire may penetrate. Hence, it is an indispensable caution for every householder to see that the chimneys are swept down, or up, at this season. A chimney may be swept from the bottom by means of a brush made on the end of an elastic pole or rattan cane, as shown at figure 1. The brush may be made of a number of goose or turkey-quills, or splints of hickory or ash, or even small twigs of trees, fastened tightly between two round pieces of thin board or sheet-iron. This brush is fixed to the end of a long, slender, limber pole, or rattan, and is thrust up the chimney from the fireplace. A very light brush and pole only are needed, as the least touch is sufficient to bring down all the soot and dust that may be adhering to the sides of the flue or resting on the slopes of it. When the chimney has been swept for the length of one pole, a second one is spliced to the first, and this is repeated until the whole of the flue is cleaned. To prevent the entrance of the dust into the room, any more than can be avoided, a cloth of some kind should be fastened over the fireplace to confine it in the chimney. The sheet may be held upon the mantel-piece by placing sad-irons upon it, and the workman—a small boy is the best for this purpose—may be covered by the sheet, having the nose and mouth protected by a wetted handkerchief tied over them. This method, however, should only be used when it is not possible to get at the chimney from the top of the house. When this can be done, the work is much less disagreeable. It will be found best in this case to get the brush to the bottom before sweeping, and then work upwards,

Fig. 1.

lest by beginning to sweep from the top the dust and soot may choke the flue part way down, and thereby cause much trouble to clear the obstruction.

### The Carrot-Basket.

A very pretty hanging-basket can be made from four or five inches of the top, or crown part, of a large carrot. The inner portion of this upper end of the carrot is to be removed with a knife, leaving a shell about half an inch thick. Three or four cords are fastened to the rim, and the basket is ready to hang up at a window. The cavity of the basket is to be kept filled with water, and care taken

that it does not become dry. After a while the carrot will start into growth, and as the delicate, finely divided leaves appear, they will turn upward on all sides, and soon cover the little basket, with here and there the orange-color of the carrot showing through with good effect. Should the leaves need "training" to arrange them satisfactorily around the basket, it may be easily done by means of a

A CARROT-BASKET.

thread passed around them, or a bent pin stuck into the carrot, may be used to hold a leaf in place.

### Household Notes and Queries.

**PLACE FOR FLOUR.**—Flour, like milk, though not so much so, is affected by bad odors of any kind, which it readily absorbs. Hence it should never be kept where vegetables, onions, etc., or fish, and such odorous things are stored. Flour should always be kept in a sweet, dry, cool, and airy room.

**PAPER AND STRAW UNDER CARPETS.**—In putting down the carpet for the winter, do not forget that a layer of paper should be first spread over the whole floor. Thick, coarse, and porous paper is made for the purpose; it is in a continuous sheet, and may be had at the carpet stores by the yard at a low price. Another material is made of two sheets of brown paper with a thin layer of cotton batting between them. In the absence of these, newspapers will answer about as well, and be much less expensive. Several layers of newspaper may be put down, or a single thickness of papers, over which is placed a thin layer of straw and other papers over this, putting in a tack here and there to keep all in place while putting down the carpet. Either of these will cover all holes and keep out the cold air, while the straw will give a soft surface to walk upon and greatly help to save the carpet.

**A USE FOR FRUIT CANS.**—Take round fruit, or vegetable, cans and melt off the top; bend a hickory withe for a handle, as shown in the engraving, and fasten it with wire or rivets. This makes a useful dipper, pitcher, measure, or vessel for many purposes about the barn or house; one may be made for the flour barrel; another for the sugar barrel or box; others for feed boxes, grain boxes, and for use in feeding poultry. In short, some 20 or more can be made useful on every farm or in every house, and as many dangerous nuisances, when these are lying about, will be got rid of profitably.

THE CAN CUP.

**THE PUTTING TOGETHER.**—A Michigan lady, Mrs. C. P. F., some of whose recipes have been sent to us, very properly says: There is so much in the

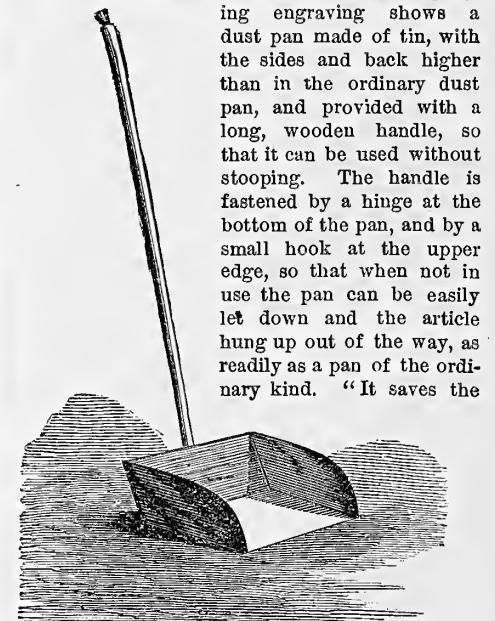

putting together the ingredients that I hesitate to send recipes—so much depends upon one's own experience. There are very few who can handle a mere recipe. It makes a great difference just when you add the butter, the sugar, and the flour, and how the mixture is worked. It is no mystery to me that there are so few good cooks. To a very few the right method comes by intuition, but to the most, only by many sad failures, and a life-long watching. I think I am just as anxious about the bread now as I was 15 years ago, and there are some things I cannot see the reason for even now.

**ORANGE CAKE.**—Miss J. Van I. sends the following: 5 Eggs, 3 cups Sugar, 1 cup Butter, 1 cup Milk, 1 quart Flour, 3 teaspoonfuls Baking Powder. Bake in round tins like thin Washington Cake. Take the grated rind and juice of 2 Oranges, the whites of 3 Eggs, and Sugar to taste—usually less than one cup. Mix well, and spread between each two surfaces of cake, and it will flavor the whole.

**WHITE MOUNTAIN CAKE.**—Butter, 4 lb.; Sugar, 1 lb.; Flour, 1 lb.; Milk, 1 cup; Yolk of 6 Eggs; Whites of 3 Eggs; Soda, half teaspoonful; Cream of Tartar, 1 teaspoonful. Put the soda into the milk, and cream of tartar into the flour. Put in a little milk, and then a little flour, and so on. Add the whites of the eggs the last thing. Flavor with Lemon. Bake in thin layers, every layer iced, and the top covered with icing. Make the frosting with the white of three eggs and 4 pound of sugar. Eight layers will be sufficient for ordinary cake.

**TEA CAKES.**—"Miss A. R.," Grand View, Iowa, recommends the following as very nice. Two cups sour Milk, half a pint each of Shorts and Rye Flour, three Eggs, well beaten, one teaspoon each of Soda and Salt, Butter the size of a hen's egg, mix and bake in gem-pans, those of iron being the best.

**A LONG HANDLED DUST PAN.**—The accompanying engraving shows a dust pan made of tin, with the sides and back higher than in the ordinary dust pan, and provided with a long, wooden handle, so that it can be used without stooping. The handle is fastened by a hinge at the bottom of the pan, and by a small hook at the upper edge, so that when not in use the pan can be easily let down and the article hung up out of the way, as readily as a pan of the ordinary kind. "It saves the

back" of the housewife, and this is enough to commend the dust pan to general use.

**SPLITTING PAPER.**—In selecting articles for a scrap-book, it sometimes occurs that one wishes to save the matter that is on both sides of the clipping. This may be done by splitting the paper. Place the paper under a piece of glass, so that it will be smooth, after which it is thoroughly soaked with water, when, with a little care, the upper surface of the paper can be entirely removed. The process is as much a matter of curiosity as utility.

**VENTILATION OF ROOMS.**—In winter it is one thing to keep dwelling rooms warm, and another to have them well supplied with pure air. There is nothing so abundant in the world as good, wholesome air, and nothing which we so seldom find in sufficient quantity in living rooms. We are apt to forget that air once breathed is not fit to breathe again, and only throw up the window or open the door when the air gets so bad as to cause a feeling of oppression. The air of a room should never get noticeably impure. Some rooms are "by nature"

provided with ample ventilation, and through the cracks the pure air finds abundant access, but most apartments, if not looked to, will limit the supply of oxygen and supply its place with the heavy noxious carbonic acid gas, which is the great source of dull head aches and sluggishness of mind and body.

In winter every sleeping room had better be a little cool than not be abundantly supplied with pure air. One should see to this on going to bed, and so adjust the window sash that there will be a proper supply of good air all through the night.

**A HANDY TOASTER.**—"W.W.B.," Unionville, Md., sends sketches of a Bread Toaster which he considers the best he has used. It is made of stout wire; the part to hold the bread is bent as shown in figure 1.

Fig. 1.—THE BREAD FRAME.

The ends *a*, *b*, being turned to form rings into which the hooks in the handle (fig. 2) fit. The bread is put between

Fig. 2.—THE HANDLE.

the wires and is easily reversed by turning the handle over half way by an easy twist of the wrist.

### Carrier for Large Jars or Cans.

Large jars, cans, or kegs, are unwieldy to handle when filled, and it is difficult to pour anything out of them. The French people use a very convenient carrier for the purpose of holding and tilting such vessels. This consists of a bottom board, to which are fixed two sides partly rounded and braced, as shown

Fig. 1.—THE JAR UPRIGHT.

in the engravings. (See figs. 1 and 2.) Side pieces having a number of holes are fixed to the upright posts of the sides. These are for the purpose of

Fig. 2.—JAR TILTED.

arranging a strap or band to confine and secure the jar at a proper height. The jar, can, or keg, is placed on the bottom board and fastened. When it is to be tilted to pour out the contents, it is simply rolled over, as shown at figure 2, and may be drained to the last drop. Kegs may be provided with spigots, having the orifice at the end, to be closed with a peg; the keg may then be easily emptied through the spigot without spilling a drop.

### Family Wastes.

It is often said, that the wastes of the household would fertilize a half-acre garden, if they were properly saved, and applied. The statement is undoubtedly true, but the if is the most important factor in the proposition. As a matter of fact, most families in the country, and villages, pay the least possible attention to these matters. The sink drain usually pours its contents upon the surface of the ground, within a few feet of the dwelling, and not frequently, close by the well. A square rod or

two of garden soil, is fattened, and kept soggy with water, and bad odors prevail through the summer. If a pear-tree, or grape-vine, happens to be planted within reach of this liquid manure, the abundant, and perfect fruit, show the value of the riches, that are wasted at this point. There is no burial of offensive matters, no utilizing thereof for the feeding of the soil, and the sustenance of the household. All these gross violations of the conditions of health, and of good husbandry as well, are justly complained of by our Boards of Health. If their Reports could be circulated among those who are most needy of their counsels, it might remedy the evil. Their teachings should be circulated in the journals that reach these families, and secure the needed reform. As a rule, any provision for the disposition of fecal matters, that does not absorb all odors every day, is defective. The most common provision, without a vault for absorbents, is a nuisance that ought to be abated, by civil enactments, with severe penalties.

The earth-closet system is effectual, if faithfully carried out. It needs, however, more executive ability than is ordinarily found in the head of the family, even if he be a cultivator of the soil. The best arrangement, on the whole, that we have observed, is a vault large enough to contain all these wastes for six months of the year, made of stone, or brick, and lined with hydraulic cement. This effectually prevents all escape of poisonous matters into the well; a matter that the head of the household can afford to secure at any cost. By the occasional use of absorbents, all the fertilizing material that falls into the vault is preserved. Offensive odors, if they arise, may be corrected by the use of Copperas. With such a vault, the gardener has a constant fountain of liquid manure, which may be applied to his growing crops through the season. The luxuriant growth of vegetables, the splendid berries, the purple clusters of the vine, and the

Fig. 1.—THE CONSTRUCTION OF THE LIFTER.

ruddy cheeks of the pears, grown under frequent applications of liquid manure, will compensate any man for the trouble and expense of this vault.

### A Pie Lifter.

Mr. R. N. WARING, Blair Co., Pa., sends sketches and description of a pie lifter. "It consists of a wooden handle about 15 inches long, to which are suspended two rectangular claws 5x6 inches, of  $\frac{1}{4}$  in. steel (or iron) wire. One of these claws is immovable, and is looped near its point of attachment to the handle (*a*, *a*); these loops admit the ends of the claw, as shown in figure 1. In using the lifter, the 'clips' *b*, *b*, of the immovable claw are brought under and against one side of the plate or article to be lifted, then by a twist and a light downward and forward motion of the handle, the clips *c*, *c*, of the movable claw, are brought in position on the other side. The second figure shows the lifter in place for carrying a pie. If properly made it

Fig. 2.—THE LIFTER AT WORK.

will grasp articles within the reach of its claws, with firmness. I do not think it is patented.

## BOYS & GIRLS' COLUMNS.

### The Doctor's Talks.

At the beginning of a new year I would say a word to the new boys and girls:—by "new," I mean those—and there is often a large number, who come into our wide family for the first time. For some months past I have been trying to talk to the youngsters about some things which are seldom taught in ordinary schools, but which every boy, and girl too, should learn while young, else they will be obliged to learn them here and there, and sometimes by experience later in life. I do not think that I have given any distinct name to the subject of these talks. If I should call it "Natural Philosophy," or "Physics," either would prevent many of you from reading them, and they would be too high-sounding for these familiar talks on common things—there; that's it! "Common Things," is the very title I want. These talks on Common Things, then, began by my trying to answer a question about the Centre of Gravity; this made it necessary to talk about Gravity. As Gravity is exercised by all matter, the late talks have been about Matter, and its properties. Matter, as has been explained, does not mean any particular substance or thing, but applies to every thing that our senses can tell us about, everything that occupies space. The principal properties of matter, that is *hardness, brittleness, elasticity*, and others, have been described, and now we have come to talk

### ABOUT MATTER IN MOTION.

If asked what *Motion* is, I think you will not find it difficult to answer—"a change of place." But nothing starts into motion or changes place of itself. You hold a marble in your fingers and drop it, the marble starts into motion and falls to the floor; in this case the motion is caused by the attraction of the earth, or gravity, which has already been described. The marble will remain where it fell for any length of time, but by pushing it with your fingers, you may send it rolling across the floor. You may move in a wagon with rapid motion, and still more rapidly in the railroad cars. A bullet shot from a gun moves still more rapidly.

### ALL MOTION IS PRODUCED BY FORCE.

And we may describe a force as whatever causes a body to move, or if moving makes it stop. The marble falls by the force of gravity; it goes along the floor by the force of your fingers; the wagon goes along by the force of the horse; the railroad train moves by the force of steam in the locomotive, and the bullet is put in very rapid motion by the force of the powder burnt in the rifle. You will see from these examples that there are various forms of force, but we will not talk about these now, but consider the force as the same, no matter how it is produced. The marble upon the floor will not start into motion of itself. This inability of bodies to start into motion

### IS CALLED INERTIA.

*Inertia* is a Latin word, and means inactivity. When told that *Inertia* describes the fact that a body can not of itself start into motion, you can understand that, but when told that it also expresses the fact that a body in motion can not stop of itself; you will perhaps stop and think about it if it can be so. Yet it is the fact that a body in motion can no more stop of itself than it can start of itself. It requires a force to start it, and when once in motion it requires an equal force to stop it. The marble in motion on the floor or the bullet from the rifle having no power to stop themselves would go on forever, were they not stopped by other forces. The marble is stopped in part by the resistance the roughness of the floor offers, and in part by the resistance offered by the air; so the bullet is in part stopped by the resistance of the air, and in part by gravity, for when the bullet is flying with almost lightning-speed, gravity is acting upon it and it is all the while falling just as certainly as if it had been merely dropped from the muzzle of the rifle. Those who fire

Fig. 1.

Fans revolving in a vacuum.

### AT A LONG RANGE TARGET

have to take both these influences into account, and to overcome the tendency of gravity to bring the bullet to the ground, must aim far above the target in order to hit it. The resistance of the air to bodies in motion is shown by the arrangement in fig. 1. In this there are two fly-wheels made of thin brass, *a* being placed with the vanes edgewise, and *b* with them flat-wise to the air; *d* is a contrivance for setting them in motion with the same force applied to both. The whole is covered by a large bell of glass. When set in motion, which is done by

pushing down the knob at the top, both will start off alike, but soon *b* will "slow up" and soon stop, while *a* is going on almost as lively as ever. The whole is then placed upon an air-pump, and the air is pumped out of the glass. The wheels are then started, and both will continue to go alike, and one will not stop before the other. But you can easily test the resistance the air makes to moving bodies without such an apparatus, by taking a piece of pasteboard, or even this number of the paper, and move it first edgewise, and then flat-wise against the air. That a body in motion requires a force to stop it may be shown in a striking manner by trying to stop a grindstone that you have set to turning rapidly, by taking hold of the handle.

#### FOR ILLUSTRATING INERTIA

there is an old fashioned piece of apparatus, shown in fig. 2. Upon a little pillar at the right hand is placed a card, and upon this is set a marble. There is a contrivance

Inertia Apparatus.

seen at the other side by which a spring is bent by a lever, when that is pressed down by the finger, the spring is suddenly let go, hits the card, which flies out from under the marble, leaving that in its place. You can, with a little practice, show the same thing without this arrangement. Place a smooth card, and on this a coin, like an old fashioned cent, or a silver quarter dollar. Then hit the end of the card a smart flip by snapping the thumb and finger of the other hand in a manner to give the edge of the card a sudden blow, when the card will fly out, leaving the coin upon the top of the finger. It can be easily learned with a little practice. If the card were slowly pushed, instead of struck a sharp blow, the motion would be communicated to the coin, and both would go off together. Inertia, or

#### UNWILLINGNESS OF BODIES TO MOVE,

is sometimes unpleasantly illustrated in our own bodies. If we are seated in a wagon and the horse starts with a sudden jump, we go with a thump against the back of the seat, or if the seat has no back we fall over backwards completely. In the same manner if the horse is going rapidly and makes a sudden stop, we are thrown forward. The injuries in some railroad collisions are due to the inertia of moving bodies. The car coming in collision with other cars, stops very suddenly; the passengers being in motion, go forward with great velocity, and being thrown against one another, and against the seats and sides of the cars, causing frightful injuries. If you quite fill a cup or glass with water and move it suddenly, or if carrying a cup or glass and are suddenly stopped, the liquid in either case will be spilled. If a boy throws a stone and hits a window, the pane will be shattered—as many a boy knows to his sorrow, but if a rifle ball hits the glass, generally, only a small hole is made, the inertia of the surrounding glass holding it in place, the ball passing so rapidly that motion is not communicated to the rest of the glass. We will not go beyond this—which is in some books called

#### THE FIRST LAW OF MOTION,

which is "The inability of a body, whether when at rest, or in motion, to change its state." There is more to say about motion, and in the next talk on the subject I can give you more illustrations on this, one of the Common Things. The two here given are from Mr. John J. Thomas' excellent work on "Farm Implements and Machinery."

#### A Little Puzzling.

If one takes 16 objects, as grains of wheat, or beans, and arranges them in the position shown in the accom-

ppanying engraving, it will be seen that there are four rows of beans of six in a row, that is—there is a row of

six on each side. This may be made clear by simply covering up all but one side or row. Four more beans, or whatever may be used for the puzzle, are now to be put into these four rows of six in a row, so that there will be no more rows, and no more in each row. If it is thought necessary to move the objects already arranged, the liberty is granted, but remember that the 20 beans are to be put in four rows of six in a row. Remember that.

#### Can a Thing Move and Remain Still?

This question was proposed in May last, as those who have last year's volume can see by turning to page 193. It was there shown that a figure, which was printed upon the page, could be made to appear to be in rapid motion, while you were all the while sure that it did not move at all. This is only one of many cases in which we do not

see things as they really are, or as it is commonly called "an optical illusion." If we try we can cheat our own eyes and those of others very readily; the illustration given in May last shows one method, and we have, in former years, given several others. In May there was a single figure of circles within one another. Prof. J. P. Thompson, of Bristol, Eng., has improved upon that in the manner shown by the engraving here given. You have only to lay the paper upon the table, or hold it flat before you, and move it in a circle, when you will see the whole series of black rings going around in a most amusing manner, while the toothed wheel in the center goes in the opposite direction. It will be all the more interesting if you copy the figure on a white card in ink, as it is more easily moved than the paper, and other things are not around it to take away the attention.

#### A Boy's Tool-Tray.

One of our young friends, "W. R. L., Stottville, N. Y., sends a very neat drawing of a Tool-Tray, together with a very nicely written letter. We have had an en-

BOY'S TOOL-TRAY.

graving made from the sketch, though on a smaller scale, and are sure many of the boys of the *American Agriculturist* family will be pleased to see Master L.'s Tool-Tray. Most boys have a pocket-knife for their first mechanical tool, and this is carried in the pocket. A hammer usually comes next, and if the work was at all in proportion to the noise it turns out, would be a wonderful tool. Other tools are added, some of which go into the all-capacious pocket, while others are kept here and there, usually where they were last used—if one could only recollect where that is. As tools accumulate, there must be, after a while, a place to keep them—a chest is hardly needed yet, and a tool-tray will answer at first. Master "W. R. L." thus describes his Tray:—"It is 18 inches long, 12 inches wide, and 3 inches deep. The central division forming the handle, should be 6 inches high in the center, and worked down to 3 inches at each end. In the center of this a piece is sawed out large enough to admit the fingers to pass through, thus allowing the tray to be carried with ease. In one of the two divisions thus formed, another piece is inserted, making two smaller divisions, and in this, as well as at each end of the tray, places are sawed down to the depth of about 2 inches, to admit the square, saws, and tools of that kind. By placing the saws and square in these slots, they are always held in their proper places. The other tools may be carried on the other side of the tray."—The Tray should be made of 1/2-inch stuff. The measurements are all of the inside.—W. R. says: "I have always been very fond of tools, and have always used them more or less, and this tray is one of my own devising, and I find it very convenient for carrying tools from one place to

another on the farm."—Here is a strong argument in favor of parents encouraging the boys to become handy with the tools in the shop, accustoming their hands to make, and their wits to contrive, the many little convenient things that go so far in the farmer's every-day life.

#### Our Puzzle-Box.

##### ADDED HEADS.

(To the word which fills the first blank, add a primal letter for the second blank—e. g., "The—made the—grow finely." "Rain, grain.")

1. The little—tore all the—off his sister's dress.
2. We often—through that lovely—.
3. Round the—of the field was a beautiful—.
4. He ran the—into his finger and began to—.
5. The dog had a sore—and was as cross as a—.
6. When I went to the—I took my cousin—with me.

##### STORE-KEEPER'S PUZZLE.

Five letters are all that are needed to form an important request.

- The first and last letter name a vegetable.
- The second letter is the initial of a large snake.
- The third letter is your own initial.
- The fourth letter is the initial of the first name of one of our Presidents.
- The fifth letter is the same as the first.

##### OBEY THE INJUNCTION OF MY WHOLE.

##### DOUBLE ACROSTIC.

The initials name a famous General, the finals, where he was defeated.

1. Of little breadth.
2. A city in Pennsylvania.
3. A river in North America.
4. A river of Asia.
5. A city in England.
6. The residence of the Spanish Kings.
7. A river of South America.
8. A territory.

JOHN W. WHEATLEY.

##### CONCEALED BIRDS.

1. I caught the owl in Netley Abbey.
2. Who now rents the Mansion House?
3. The widow Drummond over the way.
4. Her only son keeps it.
5. I think it equal to the very best.
6. Cousin Tom now lets lodgings.
7. He never fails to attend the concerts.
8. Crowds attend nightly.
9. The pond was overgrown with rushes.

##### BIBLICAL NUMERICAL ENIGMA.

- I am composed of 29 letters:  
My 1, 12, 19, 4, 13, 23, 15, was a province of Syria.  
My 5, 17, 1, 8, 11, 7, 8, was a Corinthian convert under Paul's preaching.  
My 8, 21, 16, 4, 24, 10, 14, is a bird which feeds mostly on winged insects.  
My 12, 16, 18, 6, 17, 5, 15, is an evergreen tree.  
My 16, 12, 1, 23, 3, 26, 20, is a fallen angel referred to in Revelations.  
My 17, 1, 27, 9, 12, 26, 14, is a beautiful natural phenomenon.  
My 23, 2, 17, 10, 29, 13, 23, was a reservoir of water at the foot of Mount Zion.  
My whole is part of a verse of the Bible. ISOLA.

##### ANSWERS TO PUZZLES IN THE NOVEMBER NUMBER.

NUMERICAL ENIGMAS.—1. Honesty is the best policy. 2. Constantinople, in Turkey.

DECAPITATIONS.—1. Wheat, heat. 2. Ebony, bony. 3. Atom, Tom. 4. Tura, urn. 5. Hour, our. 6. Eat, at. 7. Roar, oar.—WEATHER.

METAGRAM.—Breath, in which can be found—hear, bat, hart, rat; hat, heat, herb, heart, rate, tar, tea, bar, ear, earth, era, bath, tear, and tare; are, ate, bare, bet, eat, beat; bate, bathe, hate, and hear.

DROP-LETTER PUZZLE.—1. Groundless. 2. Condescension. 3. Procrastination. 4. Impracticable. 5. Incarcerated. 6. Characteristic. 7. Expostulate. 8. Incapacitated. 9. Disciplinary.

ILLUSTRATED REBUS, No. 470.—I show myself deserving of misfortune in deriding it.

#### A Coconut Tree Afloat.

One of our young friends, "T. A. S.," who lives in Jamaica, thinks that the following may interest his "young fellow readers outside of the tropics." How many of you can tell, without looking, what and where Jamaica is? to what country it belongs, and what its principal city?—"T. A. S." has already given you a hint that he lives in "the Tropics." Let us hope that he may tell us more about tropical matters. Here is his account: "Sometime last year, when the barometer indicated foul weather in the vicinity, the inhabitants of a small port in one of the Bahama Isles, had their attention di-

reected to a curious object floating in the offing. Some said it was one thing, some another; at length a boat's crew pulled out to the supposed disabled ship, and what do you think it turned out to be? A large and perfect Cocoon Tree floating upright in the ocean! heavy rains had probably loosened the soil on some precipitous hill-side on the coast of Cuba or Saint Domingo, and the whole tree, with a mass of earth and stones, enclosed by its thickly matted roots, had slid into the sea, or possibly been washed down by a flooded river—the stones and earth entangled in the roots served to keep the tree upright, and the buoyancy of its immense outspread leaves prevented it from sinking. This tree contained a full crop of fruit in every stage of growth and maturity, from the tiny nutlet, smaller than a hen's egg, to the ripe nut ready to be converted into oil, etc., as well as that intermediate stage when the fruit supplies a deliciously cool refreshing drink and soft jelly-like meat, which I am sure my young fellow readers would enjoy if they should pay a visit to Jamaica, or some tropical land."

### Forfeits for Fun.

In the evening games of winter gatherings of young people, and older ones too, it often becomes necessary to punish some one, or more, of the company by imposing a "Forfeit." The penance should be something that either is not easy to follow out to the letter—that is, has some catch in it, or puts the person in a conspicuous and amusing light. In all cases a forfeit should be designed to amuse the company as a whole, and never to offend the person called upon to pay it. In order to illustrate our idea of a good forfeit, and also to furnish suggestions to those who enjoy and take part in such pleasant amusements, we give a few of the forfeits that may be imposed. (1) Put a newspaper upon the floor in such a way that two persons can stand on it and not be able to touch each other with their hands.—This forfeit has the honor of being old, but it was not our good fortune to meet it until a short time ago, and was forced to "give it up." By putting the paper in a doorway, one-half inside and the other outside of the room, and closing the door over it the two persons can easily stand upon it and still be beyond each others reach.—(2) To go out of the room with two legs, and come in with six.—Not difficult if one thinks to bring a chair along on the return.—(3) To act the Dumb Servant.—The person who has the forfeit to pay must act out the answers to the questions put by the master of the ceremonies; as, How do you make bread? How do you eat soup? etc. This forfeit will cause much merriment if proper questions are put.—(4) Put one hand where the other can not touch it.—One can get out of this difficulty by putting one hand on the elbow of the other arm.—(5) Place a pencil on the floor so that one can not jump over it.—May be done by putting it close to the wall of the room.—(6) Put a question that no one can answer with a NO!—This is not hard if one thinks to ask, What does YES spell?—(7) Push a chair through a finger ring.—This forfeit is made by putting the ring on the finger and pushing the chair—any other object will do as well—with the finger. This last much resembles the next.—(8) Put yourself through a key-hole.—This was a great puzzle to us for a while, but when a piece of paper was taken with the word "yourself" written upon it, and pushed through the hole, it was all clear. There are many other of these amusing little tricks, but these given will suggest others, and help to make the social winter gatherings the enjoyable times that they should be.

No. 472. Illustrated Rebus.—One of the many very wise sayings given to us in the Proverbs.

### A Pile of Winter Wood.

The season for getting together a good, large pile of wood has come, and many of the boys and girls take a lively interest in this important work. It is fun for them to be where the chopping is going on, and to run away with half frightened glee when the trees begin to crack and fall. And then it is such nice sport for the boys to get on to the load—astride a large log, it may be—and ride home. When the pile is finished, the sawing machine comes to saw up the wood, and there is as good as a holiday for the young of the whole neighborhood.

We have been getting up a pile of wood too, and it is our plan to have the boys and girls point out the different kinds of wood that we have gathered together. There are sixteen kinds—rather more than in most wood-piles. The first block we will look at is from one of the finest of American forest trees; not large, bark very thick, young limbs armed with prickles, leaves something like those of the rose, flowers fragrant, and in large showy clusters, bearing pods in autumn. Do you recognize it?—The second kind is an evergreen, the leaves, like little needles, remaining all winter. It bears cones 2 to 4 inches long. The tree grows in wet ground, and is not very good for wood; we cut it because a road is to be put through where it stood.—Upon a bank near the low ground No. 3 was cut; it is also an evergreen, and a very common one, often growing to a large size. The wood is coarse and light, and full of splinters when split. The leaves are lighter on the under side than above. The

branches are used by boys for making bows and whistles.—No. 4 is a wide-spreading and lofty tree, and when given space in an open field, is noted for its grace and beauty. The leaves are notched along the edges, and a little larger on one side than on the other. Boston had a famous tree of this kind until it was blown down and destroyed a few years ago. New Haven is often called the "City of —." There is another kind, the inner bark of which many people like to chew.—Under favorable conditions, No. 5 grows to 30 feet in height, but it is at most a small tree. The bark is loose, and in thin square patches. In early spring this tree is covered with a profusion of white flowers like a full blown apple-tree. The berries are red in autumn, bitter, and not fit to eat. The Bark may help you to distinguish it.—No. 6 is one of the leading trees in many American forests, and makes an excellent fire wood. The bark is smooth, and trees that stand by the road-side are usually carved and disfigured with names and dates. The nuts are larger than, but in shape resembling a kind of grain sown late in the season, from the flowers of which bees make much dark honey. The Blue kind is a different and much smaller water-loving tree, with tough limbs. This kind has held a high place in the education and correction of unruly youngsters.—No. 7 is too valuable as lumber to be often found in the wood-pile, except in those regions where it is almost the only tree, and where hundreds of men are employed during the winter in getting out the logs. This wood is fine for whittling, white, light, and soft, and is excellent for kindling.—A handsome, rough-barked, slender, yellow-limbed tree, with long drooping leaves, partially fond of the water, is our No. 8. Do you find it? There are a number of kinds of it, one of which is a weeping sort, and often planted in grave-yards. The wood is light and yellow, and not of great value for fuel. The long flexible branches are largely used in basket making, and highly prized by boys for whistles.—No. 9 is a large, broad-leaved tree, with very light, white wood, and tough

stringy under bark. The flowers are not showy, but the bees find them and gather the best quality of honey, in the estimation of many. The wood is of little value for fuel, but is used for light lumber, as the thin stuff used in small boxes.—A small tree (we are sorry the artist has forgotten this) that grows in poor sandy soil is No. 10. The botanists say of it, "The cup, very thick...half enclosing the ovoid nut." The more familiar kinds of this group of trees are excellent for fuel and timber, one kind especially important in ship-building.—No. 11 is a medium-sized tree, with dark-brown bark and reddish, slender, spicy, aromatic twigs. There is a kind with white outer bark, which

THE WOOD-PILE.—PICK OUT AND NAME THE 16 KINDS OF WOOD.

may be taken off in great thin sheets. The Indians were accustomed to make many of their canoes from a tree by this name.—There is one of the United States often called after No. 12, because of the tree's unusual thriftiness and abundance along the rivers in that State. The leaves are large and consist of five parts as in a "five-leaved clover," only very much larger. The flowers are large, and in great fragrant bunches, afterwards bearing large, smooth, brown nuts, unfit to eat, within a green shell or covering. This tree is more ornamental in the yard than valuable for timber.—No. 13 is an evergreen, growing in swamps, to the height of 30 to 70 feet. The wood is exceedingly durable, and well adapted for exposed situations, as fence posts and the like. It is sometimes called by another and a double name.—The best fire-wood in our pile is No. 14, being hard and heavy. The trees do not get very large around, but often quite tall. The wood is very strong, and is highly prized for many uses. The nuts are thick-shelled, and much sought after by the boys, who, when climbing these trees, are likely to tear their clothing on the rough, hard bark.—A pile of winter wood without No. 15 would not be complete, as it is hard, easily split, and very excellent fuel. One kind is important, from the sweetness which it contains, the extracting and condensing of which is the delight of the youth of all regions where this tree grows.—The last, No. 16, is not the best wood for burning, but the tree bears the finest nuts of the temperate zone. No tree like this takes the children to the woods so quickly after the frosts come. No tree gives so much trouble to the mother who has to patch and mend. No tree gives sharper spines or prickles for the fingers of the early and impatient visitor. No boy will suffer more and sometimes seem to get so little as with our last tree.—Thus, we have tumbled around and over our wood-pile (a single block, the artist says), and if any one is not able to tell all the kinds, it will not be because we have not tried to help by both pen and pencil.

ON THE POND IN WINTER.

Every season of the year brings its peculiar pleasures and pastimes, and none has a longer and better list than winter. It is not necessary for me to say to the boys and girls that ice furnishes fun "for the million," just because it is so smooth and slippery—if it were sticky as mud or dough, then half the joys of the out-of-door sport of winter would all be spoiled. How splendid it is that when the water gets to a certain coldness it passes into that beautiful, solid, crystalline form which we know as ice! and then the feet are shod with narrow strips of steel, and away go the happy skaters for a race. That

boy or girl who has not lived where ponds and rivers, lakes and mill-pounds, "freeze over," or living there, has not joined in the fun of a skating party, does not know how near the expert, easy, graceful skater comes to the joy of a fast-flying bird. The artist has given you a scene upon the ice that none can fail to appreciate. The small boy with his old "swan-neck" skates and awkward strides; the graceful older brother and sister, or friend, with better skates and greater skill, the patient adjustment of the straps, etc., are all shown to life; but there is one thing which, though just as natural as all these, has been left

out, and well it may—the fall! How it hurts to have the feet move on much faster than the head, until—and it don't take long—the stars shine with a peculiar lustre, and one looks to see if he is out of sight. Again, the skating may be attempted before the ice is ready, and the bold and fearless youth often finds himself a wetter if not a wiser boy. If the pond is shallow, and the bottom soft and muddy, why! it is not so very dangerous; but then it is, to say the least, provoking. But what would skating be without a fall, a bump—a regular *thump*—and a little danger now and then!

UNCLE HAL.

**WOOD SOLE SHOES.**

They wear three times as long as leather-soled shoes. Keep the feet perfectly dry and warm, and more easy to the feet, being shaped to suit the action in walking. They are particularly adapted to Miners, Farmers, Butchers, Dyers, and all classes of Laborers.

NEW

AGRICULTURAL ESTABLISHMENT.

Choice Garden, Farm, and Flower Seeds at Moderate Prices.

AGRICULTURISTS will rejoice to learn of the opening of a first-class Seed House, which affords them the opportunity of buying strictly FRESH STOCK, thereby avoiding chances of loss and disappointment, arising from planting old seeds. Particular caution on the part of buyers is necessary this year, as there is an unusually heavy stock of last season's surplus on the market. We send samples of Staple Seeds free, so that farmers can test their growth before buying.

Catalogues (unillustrated,) Free to all.

J. L. DILLON, Florist, Bloomsburg, Pa.

Pure PREMIUM BONE

What Farmers Want.

They want Pure Ground Bone! Why? because it contains those elements taken from the soil in the grain and carried away, thus impoverishing the land. Pure Premium Bone, made of dry, hard, unsteamed bones, supplies just this waste, as every farmer can learn by practical experience at a trifling cost. Send for a full explanation of how it works. Excelsior Fertilizer Co., Salem, Ohio.

NOTICE

To Every Farmer and Agent.

THE MONITOR SEED DRILL.

This is the most complete and positive Seed Drill ever invented. It is radically different from and superior to all others. It is the only machine which measures and drops the seed with a positive motion, and exactly the same amount at each foot or yard. It has been tested by 6 years' use in Massachusetts, and was awarded the highest prize at the "Centennial." The "MONITOR" has been thoroughly tested during the seasons of 1878 and 1879, and heartily endorsed as a

FIRST-CLASS MACHINE

by Professor Geo. Thurber, of New Jersey, and by Jas. Vick, of Rochester, N. Y.

Agents Wanted.—For full descriptive circular and testimonials, address

# STEEL BARB FENCE,

Solves the FENCE Problem by meeting all the requisites of  
**THE PERFECT FARM FENCE.**

**Every Land Owner** should not fail to examine the merits of this fence. It is cheaper than all others. Easiest handled, and in fact just what the people of the treeless States have needed for years.

**To All Inquirers.**

It is an impassable barrier, yet harmless. Prohibits trespassing. It can be put up by any one, and is compactly put up for transportation. In fact, it is the only fence dog and wolf proof.

**Cheaper than Wooden Fences.** Imperishable when once in place. Indestructible by the Elements. Wastes no soil by SHADE. Has no Weedy Fence Borders. Shelters no Enemies of the Crops. A Protection at all seasons. It is easy of Construction. It needs no repairs. Accumulates no snow-drifts.

## A STEEL THORN HEDGE.

**Impassable Barrier.** Prohibits all Trespassing. It can not be destroyed by fire, wind, or flood.

100,000 miles of Barb Fence have been erected in 1876, 1877, 1878. Agriculturists, Herdsmen, Sheep Husbandmen, Ranchmen, Vineyard Proprietors, Orchardists, Nurserymen, Railroad Companies, Road Proprietors, and all owners and occupants of soil and areas to be protected.

Manufactured by **Washburn & Moen Manufacturing Co.,**  
**WORCESTER, MASS., and 21 CLIFF ST. NEW YORK.**

Chicago Office, 107 Lake St.

St. Louis Office, 802 North Second St.

containing a great variety of Items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Continued from Page 8.

In justice to the majority of our subscribers, who have been readers for many years, articles and illustrations are seldom repeated, as those who desire information on a particular subject can cheaply obtain one or more of the back numbers containing what is wanted.

Back numbers of the "American Agriculturist," containing articles referred to in the "Basket" or elsewhere, can always be supplied and sent post-paid for 15 cts. each, or \$1.50 per volume.

**Bound Copies** of volume 33, and of every previous volume back to Vol. XVI. (1857), neatly bound, with gilt backs, Index, etc., are supplied at \$2 each (or \$2.30 if to be sent by mail). See Publishers' Notes, 2d cover page.

**Clubs** can at any time be increased by remitting for each addition, the price paid by the original members; or a small club may be made a larger one at reduced rates, thus: One having sent 6 subscribers and \$7, may afterwards send 4 names more and \$3, making 10 subscribers for \$10.00; and so for the various other club rates.

**Terms to New South Wales, New Zealand, Australia, Africa, etc.**—To several inquirers. Under the latest revision of the Postal Union Regulations the price of the *American Agriculturist*, (either English or German edition), including postage prepaid through, will be covered by 7 shillings sterling per annum. This applies to the above countries, and to all others embraced in the General Postal Union. The simplest mode of remittance is by Postal Money Orders, payable in London, to the order of Orange Judd Company. These can be readily cashed in N. Y. City at a slight discount, which the publishers will cheerfully pay. For Club rates, (postage included), see our second cover page, and reckon 22 cents to the shilling sterling.

**Hoose in Calves.**—"H. C. B.," W. T. The so-called "diphtheria" which killed your calves is doubtless a parasitical disease known as *husk* or *hoose*, otherwise *vermiculous bronchitis*. It is common among calves and lambs which feed in marshy or wet pastures, and often in other pastures where older animals have run. The disease is caused by the presence of white thread-worms in the air passages, which are often so numerous as to cause suffocation. The remedy is to give Turpentine in one ounce doses in milk, every morning, for a week or ten days; or to give Sulphur in 2 dram doses, every day for 3 or 4 weeks. The whole system must be impregnated with the medicine, which passes off by the lungs and the mucous secretions, but kills the worms with which it comes in contact.

**How Many Hogs to an Acre of Clover?**—"E. P.," Taunton, Mass. That depends on the kind of hogs and the sort of clover. An acre of good clover, that would cut two tons of hay, should afford pasturage for 10 hogs of 200 pounds each, if they would not root it up. It would keep more, if the clover were cut and fed to the hogs in pens, and a little meal slop given for drink.

**Bone Meal** is a valuable but slowly acting manure. Some farmers who have used it with little or no increase of the crop, the first year, have been disappointed. Bone, when used as a fertilizer, is not washed out: a great advantage in porous or leachy soils. The finer the meal is ground the quicker it is used up by vegetation—coarse meal may make its presence felt upon the crops for several years after its application.

**Lice from Birds.**—"J. C. E.," Clinton, Pa. Lice from poultry and birds will greatly annoy horses and cattle, and cases have been known in which horses have been so badly infested with them as to die under the infliction. But it is only the mature insects which give trouble. They will not breed upon any quadruped, and if the source of the annoyance is removed, the effects will be only temporary. Poultry, sparrows, swallows, owls, and other birds are usually infested with the minute lice which do the mischief. The remedy is to clear these out from stables and barns, and if necessary brush the infested animals thoroughly with a mixture of lard and kerosene oils. Smear a brush with the oils and shake it out thoroughly, and then give the coat a vigorous brushing.

## AN OLD-FASHIONED KNIFE.

Made of **Razor Steel, Hand Forged**, and made especially for rough work; blades very thick. No corners on handle to wear pockets. **By mail, postage paid, 75 cts.** Soft or flaky blades we replace free.

For lighter work we have knives of equally good steel, 50 and 60 cts. One-blade, like picture, 50 cts.; lighter 1-blade, 25 and 35 cts.

**Pruners:** Medium, 75 cts.; **Our Best**, 8 inches when open, oil temper and tested, \$1.

**BUDDING**, 65 cents; **Farriers'**, \$1.00.

This cut shows new knife, No. 21, strong, but not clumsy. Price, 75c. Same, 3-blade, \$1.00. **Pen Knives:** Gent's 3-blade, \$1.00. Fine pearl handle, 2-blade, \$1.00. Congress knife (our finest), \$1.50. Ladies' 1-blade, 2 cts.; 2-blade, 50c. List free. Discount to dealers. Address

## Poultry Exhibitions for January, Etc.

<b>VERMONT.</b>	
Champlain Valley Poultry Ass'n Burlington	Dec. 30-Jan. 1
Wide Awake Poultry Club	St. Johnsbury Dec. 30-Jan. 1
Vermont State Poultry Ass'n Rutland	Jan. 6-9
<b>MASSACHUSETTS.</b>	
Central Mass. Poultry Ass'n Worcester	Jan. 20-23
Middlesex Poultry Ass'n Lowell	Dec. 29-Jan. 2
Southern Mass. Poultry Ass'n Fall River	Jan. 19-21
<b>RHODE ISLAND.</b>	
Rhode Island Poultry Ass'n Providence	Feb. 4-11
<b>CONNECTICUT.</b>	
Meriden Poultry Club	Meriden Jan. 6-8
<b>NEW YORK.</b>	
Cortland Co. Ass'n Cortland	Jan. 20-23
Empire State Poultry Ass'n Syracuse	Jan. 29-Feb. 5
Eastern N. Y. Fanciers' Ass'n Albany	Jan. 20-27
<b>PENNSYLVANIA.</b>	
Central Poultry Ass'n Pottsville	Jan. 6-10
Huntington Poultry Ass'n Huntingdon	Jan. 12-15
Lancaster Poultry Ass'n Lancaster	Jan. 2-4
Lehigh Valley Ass'n Allentown	Dec. 30-Jan. 3
Luzern Pet Stock Ass'n Wilkesbarre	Dec. 31-Jan. 2
<b>INDIANA.</b>	
Northern Indiana Poultry Ass'n Fort Wayne	Jan. 27-30
State Poultry Ass'n Indianapolis	Jan. 8-15
<b>ILLINOIS.</b>	
Western Poultry Club	Bloomington Jan. 16-23
<b>IOWA.</b>	
Council Bluffs District Ass'n Council Bluffs	Jan. 20-23
<b>CANADA.</b>	
Montreal Pet Stock Ass'n Montreal	Feb. 4-6
St. John's Poultry Ass'n St. John's, N. B.	Jan. 20-22

**A Most Interesting and Important Article** is given on page 13. If one half the confident expectations of the U. S. Fish Commission is realized, untold millions will be speedily added to the food production of our country, at trifling cost. Not only lakes and streams, but the pools of bog-meadows and sloughs will be the best food-producing portions of the country. The gentlemen conducting the U. S. Fish Commission, while enthusiastic, are not the men likely to indulge in groundless theories. They have accomplished great things in other directions, and we are much inclined to put confidence in their promises for the Carp. Read the article.

**A House for 30 Ducks.**—"C. H. W.," Yarmouth, Me. Ducks are very dirty birds in a house and need to have considerable room. A flock of thirty will require a house 12x12 feet, which should be so made that it can be easily cleaned out. Nest places should be provided on the ground, hidden by a frame around three sides.

**The Breed for Market Pigs.**—"Rose Farm," N. J. It is a matter of dispute, and always will be, which are the best breeds of pigs for special uses. The Berkshire is black but comely, and perhaps the most profitable pig of all the breeds for pork at any age. The Essex is also black, and some think that the best, but it has the objection of having too much fat. Some will have only white pigs and the Suffolk is generally considered the best of the small white breeds; the small Yorkshire is a more modern variety, and perhaps owes some of its good qualities to a Suffolk cross. If so, it would be fair to call the Suffolk a better kind than the Yorkshire. But there are some who think differently, and no one can say confidently that this or that is the best except from his own point of view and as a matter of opinion. The small white breeds have become so much crossed and mixed, that at the English exhibitions they are no longer classed distinctly but collectively as "small white breeds."

**Poultry Disease.**—"Minnie C." sends no name or address. We do not usually answer such letters, but in this case of a little girl, we make an exception to our rule. The disease is doubtless the prevalent "cholera," so called; it is a disease of the liver and intestines, a typhoid or intestinal fever, which ends in gangrene. The fowls sit about, turn yellow about the head, void green or yellow matter and do not eat. There is no cure; the disease is very infectious and the best way is to kill every sick fowl as soon as it is discovered. Remove the well birds to a fresh place, that is clean, dry, and airy, and feed them on boiled wheat with a small tablespoonful of fine, dry lime stirred in the mess for each dozen fowls.

**Dr. Lawes' Wheat Crop for 1879.**—The following interesting figures are condensed from a communication by Dr. J. B. Lawes of Rothamsted, England, to the "North British Agriculturist." Within his memory England has never before had such a bad wheat crop as that of 1879, certainly not since 1816. Dr. Lawes is one of the most eminent of agricultural experimenters, his results being of peculiar value from their accuracy in all the details and the length of time over which the experiments have extended. He has grown the same kind of crop on the same piece of ground, and same condition as to fertilizing, and some with no manure for 36 years. The tables, which it is not necessary to reproduce, show that the continuously unmanured plots the present year gave only 4½ bushels per acre of wheat, while the average for the past 10 years on the same plots, was 11 bushels; and 14½ bushels per acre, for the 17 years just preceding the last ten years. A gradual decrease is to be expected, but not the falling off which occurred in 1879. The plot receiv-

ing 14 tons to the acre of farm-yard manure annually, gave only 16 bushels for the last year, against 34 per acre as the average for the preceding 27 years. Of the three artificially manured plots one gave 16½ bushels, or about half the average; the second, more highly manured, gave 20½ bushels, likewise a half average. The last and most highly fertilized plot, gave 22 bushels per acre, also about a half average. In 1863, the average of the three artificially manured plots was 55 bushels. In 1879, the very same plots and fertilizers, had an average of 19½ bushels, and each bushel weighed 9 pounds less than in 1863.

Dr. Lawes concludes by stating, "We have here a striking illustration of how great is the influence on the results of the farmer's efforts, of circumstances entirely beyond his control, after he has employed all the resources at his command to obtain a good crop."

**Sowing Forest-tree Seeds.**—"W. J. A. B.," Kans. We hope to give an article on this subject, before the season is at hand for sowing. Just now, the point of greatest importance is, to preserve the seeds, so that they may germinate when sown. If many seeds, the chestnut for example, are left exposed to the air, they become so dry that they can not be restored—killed in fact. All the seeds you name are best preserved in damp sand, and any others about which you are in doubt, should be treated in the same manner. While the sand should be "damp," it must not be wet. Sand as it is freshly dug from the bank, is usually in the proper condition. Enough should be used to keep the seeds well separated, so that they may not be in masses together, but equally distributed. An equal bulk is usually enough, but no harm can come from using more. The mixed sand and seeds must be kept in a cold place. In a warm one, the seeds would soon germinate and be lost. Most seeds will not be injured by freezing, and some benefited. They should be looked at occasionally, to see that the sand does not get entirely dry; if quite dry, enough water should be added to make it as moist as at first. Towards spring, some kinds may begin to germinate, and must be sown at once; indeed, early sowing is best for all. Keep the seeds during winter where rats and mice can not get at them.

**Salt for Black Knot.**—"D. D. S.," Malden, Uster Co., N. Y., asks if salt will cure black knot on plum trees. From the nature of the knot, which is described in full on page 22, we do not see how salt can be made to reach the real trouble, which is at work long before it appears as the knot. The only way is, to cut off the affected branches, and burn them. Cut several inches below the knot, as the threads run down some distance.

**A Cow with Sore Eyes.**—"L. K.," Glen City, Pa. When a cow is troubled with inflamed eyes, a cough and inflammation of the udder, with stringy milk, it indicates fever with disturbance of the lungs and circulation. The treatment should consist of a dose of 12 ounces Epsom Salts, repeated the third day, and after that 4 drams of Saltpetre, given daily; with warm barn slops, and good nursing, until the fever completely disappears.

**Electricity in Bee Keeping.**—Herr Freiurth, a bee keeper, and correspondent of the *Deutsche Presse*, has recently perfected an apparatus for quieting bees by electricity, by which they become as lifeless creatures, and remain so for from ten minutes to a few hours, the duration of the effect depending upon the strength of the current. He has used the machine for hiving the bees, and for working among them while they are in the hive, and finds that electricity does not injure the bees at all, but renders them, in an instant, as easy to handle as so much lifeless matter. We hope that some of our bee keepers, who have devised so many improvements in the apiary, will test the matter; if all that we have quoted is true, it will be of great value. Many would keep bees, if it were not for the dread of stings; this use of electricity would practically remove this obstacle.

**The Apple Leaf Fungus** was figured and described last month, p. 468, and we have since then received several interesting letters concerning it. Mr. "P. P. H.," Union, Monroe Co., W. Va., writes: "I have observed this Fungus for several years, and, of course, read the article with interest. We had a young Crab-apple tree transplanted to our yard, but the early frosts deprived us of its beautiful bloom; and the sickly, blotched foliage, made it a pitiable object among roses and other shrubs. We often discussed its removal, but the desire to see it covered with its unrivaled blossoms, led us to exercise patience. Two small Red Cedars were brought and placed near the Crab-apple, and these were soon covered with the 'Cedar Apple.'... It would seem from this that the spores were communicated from the Crab-apple tree. You say, by destroying the Cedar fungus, that upon the apple may be eradicated. Would it not be better to begin with the 'cluster cup,' the first stage of its existence?"—It would be better, if practicable. It is a much easier matter to collect the Cedar apples than the leaves of the apple trees; besides, if the

leaves are picked off in early spring, it would injure the tree.—"T. C. W.," Manhattan, Kansas, sends specimens of the fungus on the leaves and twigs of a wild Crab-apple tree, and says: "The tree grows thriftily, and looks prettily in the spring, but after a while this fungus comes on it so badly, that many of the leaves curl up and drop off, and whenever it attacks the twigs, all above the fungus dies.... There are Red Cedars all around, and plenty of Cedar apples."—We should, as this Crab-apple tree is near an orchard, cut it down, and the Cedar trees, if near by, should be looked after.

**Through a Brick.**—In September last, page 349, an engraving was given of a potato perforated by the root-stock of Quack or Couch-Grass (*Triticum repens*). It is stated in the article that another and more slender grass, the Mexican Drop-Seed (*Muhlenbergia Mexicana*), has similar, though more slender, root-stocks, which in their onward growth through the soil, penetrate any soft obstacle they may meet. Since the perforated potato was published, a friend gave us a specimen in which this root-stock had made its way through a brick! "Seeing through a brick" is a wonderful performance sometimes shown to "greenhorns," but we long ago showed the Boys and Girls how it was done. There is nothing wonderful about the passage of the root-stock through this hard substance, when we find that there was a hole through the brick. The brick was an imperfect one; probably a small twig or straw was in the clay, which, burning out, left a hole through which the grass found its way.

**A Nurseryman's Society.**—"L. B. S.," There is such a Society; we think it is not confined to nurserymen, but includes those engaged in the sale of seeds and plants of all kinds, and has for its objects, as we understand them, the better acquaintance of those engaged in kindred pursuits, and such mutual understanding as shall help one another and protect one another from the various frauds practised upon such dealers. The officers for 1879-80 are: President, T. S. Hubbard, Fredonia, N. Y.; Vice-Prest, J. T. Lovett, Little Silver, N. J.; Sec., D. Wilnot Scott, Galeana, Ill.; Treas., A. K. Whitney, Franklin Grove, Ill.; Exec. Com., with the Pres't and Sec., S. W. Hoover, Dayton, O.; Franklin Davis, Baltimore, Md.; Geo. B. Thomas, Westchester, Pa. We do not know the conditions of membership, but presume that any nurseryman, seedsman, or florist, in good standing, will be welcomed to the Society. The next meeting will be held at Chicago, Ill., June 16-18, 1880.

**Do Snakes Swallow their Young?**—Several years ago, at the request of an eminent naturalist, we asked for experience upon the above question. And abundant evidence was given to show that some snakes do take their young into their bodies. After this, it was asked if this was done by venomous snakes. On this point, "W. F. M.," Arispie, Kans., writes: "that while he and his boy during the past season killed 19 Rattle Snakes, without fluding any young within, but one of his neighbors killed a 'Rattler' containing 13, and another killed one containing 4 young snakes, which, so soon as liberated, by coiling up, rattling, and striking out at persons, showed their venomous 'Rattle Snake' nature."

**Seed Corn.**—If any one's last crop of corn was not of as good quality as desirable, and a neighbor or distant friend has some better sort, make it a business to get some of it for seed, now, and have it ready when the day of planting comes. In selecting, note the time of ripening, size and number of ears on stalk, size of stalk, quality of the grain, and all other important points.

**To Prevent Powder-Post.**—The honey-combed, powder-covered, worm-eaten, and therefore worthless state, which hickory timber will many times assume if not properly cared for, is caused by the larvæ of the *Lyctus striatus*, an insect that deposits its eggs in the soft outer wood of the dead tree, mostly during the months of May and June. If the trees are cut at a season when the soft wood becomes dry and hard before the time for the insect to make its appearance, there is no danger from this pest. Hickory cut in the winter season will generally be free from attacks, but to make sure, it is best to remove the bark, and even split the timber that it may become thoroughly seasoned. Keep it in a dry place.

**Illinois Agricultural Institute.**—The Agricultural Department of the Industrial University, Champaign, Ill., will hold its annual course of public Lectures and Discussions during the last week of January. Greater facilities for gaining information pertaining to the farm will be given than in the past, and a much larger attendance is anticipated. For farmers who have a longer time at their disposal a course has been especially arranged to extend from January 7th to March 23d, during which time daily lectures and other instructions will be given on practical farm matters. — [It is a matter of taste to be sure—but we think it not good taste for an institution called an "University" to send out its circulars in red ink.]

## Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the *American Agriculturist*, from our record kept daily during the year, show at a glance the transactions for the month ending Dec. 12th, 1879, and for the corresponding period last year:

## 1. TRANSACTIONS AT THE NEW YORK MARKETS.

RECEIPTS.	Flour.	Wheat.	Corn.	Rye.	Barley.	Oats.
25 d's this m'th	526,000	6,127,000	4,036,000	589,000	602,000	916,000
26 d's last m'th	461,000	10,170,000	4,116,000	557,000	1,193,000	1,212,000
SALES.	Flour.	Wheat.	Corn.	Rye.	Barley.	Oats.
25 d's this m'th	1,465,000	23,817,000	5,902,000	354,000	611,000	1,805,000
26 d's last m'th	1,473,000	26,839,000	6,347,000	395,000	673,000	1,796,000

\* Including sales for forward delivery.

## 2. Comparison with same period at this time last year.

RECEIPTS.	Flour.	Wheat.	Corn.	Rye.	Barley.	Oats.
25 days 1879.	526,000	6,127,000	4,036,000	589,000	602,000	916,000
26 days 1878.	475,000	4,236,000	2,434,000	387,000	743,000	831,000
SALES.	Flour.	Wheat.	Corn.	Rye.	Barley.	Oats.
25 days 1879.	1,465,000	23,817,000	5,902,000	354,000	611,000	1,805,000
26 days 1878.	504,000	5,936,000	4,094,000	411,000	609,000	1,302,600

## 3. Exports from New York, Jan. 1 to Dec. 9.

Flour.	Wheat.	Corn.	Rye.	Barley.	Oats.	Feas.
bbls.	bush.	bush.	bush.	bush.	bush.	bush.
79,344,000	62,212,007	34,105,000	4,013,000	167,000	523,000	381,000
78,243,166	52,166,952	25,844,569	3,970,465	1,518,667	645,001	428,937

PUMPKINS, per 100	—	—

Business in Government Securities, and Railway and Miscellaneous Bonds, Mortgages, and Share property has been again on the increase through recent weeks, and the speculative temper has developed more con-

dently, leading to renewed firmness, and buoyancy in prices; favored by the prevalent ease in the Money Market.... In Produce and Merchandise, operations have been also on a comparatively liberal scale,—notably so in Breadstuffs, Provisions, and Cotton, but at very variable quotations, the changes having been frequent and, in several instances, quite radical, as resulting, in great part from the speculative influences, which have been in substantial control of the Produce Markets.... All kinds of Breadstuffs have been again advanced materially, through speculative action, which has carried prices relatively much above the current figures in the Foreign Markets, (though these have shown a steadily hardening tendency), thus seriously impeding the outward movement of Flour and Grain, and leading to a rapid accumulation of supplies at the seaboard, as well as at the principal points of the interior. Notwithstanding the unsatisfactory position of the export interest, the speculative demand has been gaining in volume, urgency, and confidence, especially within the past week or two, and the loss in values, of which mention was made in our last, has not only been recovered, but prices have been pushed decidedly ahead, on the upward movement, on excited markets, particularly at the extreme close, subject, of course, to sudden and, in instances, sharp reactions, partly due to sales to realize profits. Wednesday, December 10th, was marked by a rise from the preceding day in Wheat of 2@3 cts.; Corn, 1@2 cts.; Rye, 3 cts.; Oats, 1@2 1/2 cts., per bushel; Flour, 10@25 cts. per bbl., on very free dealings, in Wheat and Corn, and an active trade also in Rye, Oats, and Flour. The transactions in Wheat were mainly in Winter grades, chiefly in the grades of No. 2 Red, and No. 1 White, on speculative account,—the operations in No. 2 Red, for January delivery, alone, having exceeded, on the specified day, 900,000 bushels, opening at \$1.61, rising to \$1.63, and receding to \$1.60 1/2 per bushel. Corn also met with unusual attention on that day, the reported sales having amounted to about three-fourths of a million bushels, of which amount about one-half was for prompt delivery, in good part for export. Of Wheat, shippers have been recently making the most important purchases of low grade, or ungraded stock, as being least affected by the speculative manipulation of values, which does not exceed much beyond No. 1 White, No. 2 Red, and the various classes of No. 2 Spring. On Thursday, Dec. 11, transactions in Wheat were again very extensive, having been, as reported, up to nearly two million bushels, (1,984,000 bushels), of which about 290,000 bushels were for prompt delivery. Most of the day's trading was again in the option line, and chiefly in Winter grades, of which, in No. 2 Red, the dealings reached 1,300,000 bushels, including for January delivery, 800,000 bushels. Prices fluctuated widely, the extremes for the day having been fully 3c. a bushel apart, but at the close the quotations stood, in most instances, 1/2@1c. a bushel higher than on the preceding day. A free export inquiry was reported, chiefly for No. 1 White for the Continent. Corn receded 1/4c. a bushel, and Oats fell off 1@2c. a bushel, on a much lighter volume of business. Rye has become quite scarce for early delivery, giving holders the advantage in all current negotiations, the market winding up buoyantly. Barley opened very brisk at advancing prices, but has recently been in limited request, and somewhat irregular. Oats have been rising steadily, on a reduced offering and active inquiry.... In the Provision line, Hog products have been remarkably active and buoyant, closing more or less unsettled. Beef and Beef Hams, firm, and in fair request. Butter and Cheese less sought after, the former yielding in price. Eggs also weaker.... Seeds have been without important alteration, and have been, as a rule, quiet, strictly prime to fancy Clover Seed having been the notable exception as in fairly active demand.... Hops have declined considerably, as influenced by the falling off in the export call, and the accumulation of stock here.... Hay and Straw have advanced, and have been in good request, with comparatively moderate supplies available.... Wool has been more sought after, and has been quoted higher, closing generally strong in price, on much lighter offerings.... Cotton has been decidedly buoyant, on a brisk movement, mainly speculative.... Groceries have been attracting less attention, and prices have been quoted weaker.... Hides and Leather, again dearer, and in light stock.... Naval Stores and Petroleum less active, and unsettled.... Metals, Hardware, and Boots and Shoes, less freely dealt in. Iron and Iron products weaker in price.... Dry Goods, on the advance in nearly all instances, and remarkably active for the season.... Ocean freights have shown much less animation, and rates have declined materially.... The closing of inland navigation has cut off one important source of supplies of produce for the winter, the great trunk railways being now the chief reliance of our merchants for the current movement of bulk freight to the seaboard. At the extreme close, the freight market was further seriously depressed, the rates on Grain, hence by steam to Liverpool, (Dec. 11), having fallen to 4c. per bushel, and by rail hence to Cork, for orders, to 5c. per quarter, and for Provisions, by steam to Liverpool, to 22s. 6d. @30s. per ton.

Dec. 8..... 6 @10 1/2 c. 8 1/2 @9 1/2 c. 8 1/2 c.

Bees.—The month's business opened briskly, with a decided advance in prices, and became stronger as the weeks elapsed. An advance of 1/4c. 3/4 lb, and the expectation of higher prices unfortunately tempted shippers to overshoot the mark, and, by crowding the market, tumbled prices down again, causing heavy losses. \$50 a car load was the figure of the loss to many, and a dull feeling prevailed up to the close; when an effort to put up the market failed, and prices remained stationary at 2 1/2@3c. 3/4 lb, live weight, for coarse oxen and dry cows; 7c. @8c. 3/4 lb for poor to fair steers, to dress 55 to 56 lbs; 9c. @10c. 3/4 lb for good to choice to dress 56 to 57 lbs, and 10c. @10 1/2 c. for selected steers on 57 lbs. estimate.

Exports have been brisk; the last week 250 live cattle, 8,627 quarters of beef; 2,150 dressed sheep, and 175 dressed hogs were shipped.... Cows.—The demand has been unusually strong for cows, and a gradual advance in prices has taken place, which the unusually heavy receipts in one week of nearly 500 head did not check. Good cows are now worth \$60 per head, and extra have sold at \$70. The range may be quoted at \$45 to \$65 per head for fair to extra.... Calves.—A steady business, with an even demand, has kept the market in good condition. Firmness, at full prices, may be said to mark the trade, for no quotable advance has been made during the month, yet the seller has been favored more than the buyer. Grassers have been steady at 2 1/2@3c. 3/4 lb alive; choice calves have sold as high as 3 1/2c. 3/4 lb. Fed calves have brought 3 1/2@4c. 3/4 lb, and veals 4 1/2@7c. for common to choice.... Sheep and Lambs.—The market for sheep has been brisk, and prices have gradually strengthened, closing at 3 1/2@5c. 3/4 lb for poor to choice. Some heavy Kentucky sheep, average 157 lbs., sold for 6c., the highest price for more than 6 months. Lambs have been less active, and 5@6c. has been paid for common to extra.... Swine.—A brisk market and somewhat higher prices are to be noted, at the fore part of the month, with a fall of 1/4c. 3/4 lb towards the close, when a firmer feeling was exhibited, and prices advanced 1/4c. 3/4 lb to 4 1/2 and 5c. 3/4 lb.

Horse Market.—Few horses are selling at present. The best indication of the condition of the horse market is the fact that dealers have shipped largely to Europe, 50 animals having been sent to Antwerp by one steamer. These were fine coach horses, and taking into account the risk of shipping valuable animals at this stormy season, it shows clearly that the home market has been without any life. One thing to be considered is, that the summer's business has cleared off most of the good stock, and there are few left in breeders' hands, so that while sales are few and far between, prices remain stationary. A few work horses are always called for to fill vacancies, and just now this is all that is doing.

## Prices of Feed.

Bran, per ton.....\$16.00 @ \$18.00

Middlings, per ton..... 19.00 @ 20.00

Ground Feed, per ton..... 21.00 @ 23.00

Walton, Whann & Co's Raw Bone Phosphate..... 40.00

Gypsum, Nova Scotia, ground, per ton..... 7.50

Home Made Bone Fertilizer.—"W. S. S."

In some localities, which are distant from markets or

large towns, it may be found convenient for farmers to do the best they can to procure waste bones, and reduce them to a condition for use by means of wood ashes, as was explained in the *American Agriculturist* for Nov., 1879, (page 477). But where manufactured bone dust, or other bone fertilizers can be procured, it will certainly not pay for farmers to spend money and time in the disagreeable and slow process of thus reducing bones for use. Their money may be better used in purchasing the more effective fertilizers, and their time in doing more valuable work. The hints given to a correspondent last month, were not intended to be of general application, as W.S.S. and some others have supposed, but only to apply to special cases, where raw bones were easily procured, and the manufactured bone was not.

**Balky Horses.**—After long coaxing, with no little use of the whip, we have seen a balky horse started by putting a lump of earth in its mouth. The mind of the animal seems to be set on not going, and the point to be gained is to divert it from the idea entertained, and thus the earth in the mouth does effectually. So soon as the horse gives its attention to the getting of the earth out of its mouth, it forgets its balkiness and can be started.

**Keeping Butter with Borax.**—The Italian Minister of Agriculture gives an account of experiments which have been made at the Experimental Station at Florence, to the effect that Butter, purposely not freed from buttermilk, kept perfectly sweet for upwards of three months by the addition of about eight percent of Borax. It is stated that the Borax should be dry, in fine powder, and thoroughly mixed with the butter. A friend of ours is experimenting with both Borax and Boracic Acid, in butter, and will in due time report results.

**The Gardens and Conservatories of California,** is the title of a series of articles by Mr. Shinn, the Editor, the first of which appears in the "California Horticulturist" for November. This article is illustrated by a full-page photograph of the residence of A. K. P. Harmon, of Oakland, giving the house, grounds, and a large conservatory. A comparison of this fine place with our recollection of a visit to Oakland, shows that twenty-five years must have brought wonderful changes in what was then a very rude suburb of San Francisco. But this is not more wonderful than that San Francisco should publish the second Horticultural journal of the country—our old friend the "Gardener's Monthly" being the first. More wonderful still is the fact that for our third horticultural journal, we must still go to the Pacific coast, where the "Southern California Horticulturist" is doing most excellent work for its favored locality. We use first, second, and third, with reference to duration, not to indicate order of excellence, which we should not attempt where each is so good in its place.

**The 10th Duchess of Airdrie,** owned by Hon. Mat. Cochrane, is one of the most remarkable cows on record. She has just given birth to her ninth calf; the "8th Duchess of Hillhurst." Of the 10th Duchess and her daughters, Mr. Cochrane has sold several animals at the price named: "4th Duke of Hillhurst, \$7,000; "5th Duke of H." (2 months old), \$8,000; "Duchess 5th" (8 months old), \$18,000; "Duchess 2d" (cow), \$21,000; "Duchess 3d" (heifer), \$23,600; "6th Duchess of H." (heifer), \$12,000; "3d Duchess of H." (heifer), \$20,500; "5th Duchess of H." (heifer), \$21,500; a total of \$131,600 for the eight animals. The 10th Duchess, Airdrie Duchess 4th, and the 7th Duke and 7th and 8th Duchesses of Hillhurst are still in Mr. Cochrane's possession, valued at \$116,000. Grand total from the "10th Duchess of Airdrie," \$247,600. Not a small sum for one cow.

**The Rennet Plant.**—A friend writes from Idaho that he has heard of a plant growing in New Mexico that is used in cheese making for the same purpose as rennet. Will some of our subscribers in New Mexico tell us what this plant is, or, if the botanical name is not known, send a specimen, that we may determine what it is?

**Hop Culture.**—"H. D. M." St. Louis, Mo., asks a series of questions which would require a treatise to answer in full. Perhaps an answer to the first may make a reply to the others unnecessary. He asks: "Can Hops be grown to advantage on a wet, mucky soil, not springy, but a marsh, subject to overflow in winter or spring?"—Most decidedly not. The first requisite in Hop culture is a dry warm soil, if at all retentive of water the plants will soon die out. It would be a waste of labor and a useless expense to set a hop-yard on such soil like that described.

**Value of Fodder Corn.**—The experience of the past season has given the writer a highly favorable opinion of fodder corn. A number of cows kept for milk have been steadily fed from July until frost upon fodder corn, with the addition of four quarts of meal daily. The ration has been 90 lbs. in three meals of 30 lbs each. The

first feed was given at 6 o'clock in the morning, cut up in a fodder cutter, wetted with water in which malt sprouts had been steeped for 12 hours, 2 qts. for each cow, and sprinkled with 2 quarts of meal of corn, oats, and wheat-middlings ground together; the second at noon, given whole, and the third at 6 o'clock in the evening, cut as in the morning, but without any malt-sprouts and with 2 qts. of meal, mixed with it after wetting it with water. Upon this feed the cows have kept up their usual flow of milk and in good condition, and have done as well as when fed upon green clover or grass. The corn was sown with the Albany corn planter in drills 3 feet apart and 3 inches apart in the drill. Five feet of row produces 30 lbs. of fodder, or 2 lbs. to the square foot, or 43 tons to the acre, the corn being about 8 feet high and having a good many half-grown ears here and there. One acre of such corn is thus able to support 40 cows 13 days, or 12 cows for 40 days; but this is only when fully grown, as it was when these weights and measures were made. Half of this estimate would be fair, considering that the feeding of the fodder usually begins when a part of the field is only half-grown. It may be gathered from these facts that there can be no more valuable fodder crop grown for late summer and early fall feeding than fodder corn. This experience is corroborated by that of many other dairymen and farmers, but it is worth noting that there is a difference in fodder corn which may well account for the various opinions regarding it. There is that which, sown broadcast and being too much shaded from light, is without color or substance, and makes very poor feed; and that, on the other hand, which having been grown in rows and exposed to the light is more solid and the juices are more mature and perfect. The latter kind is that which satisfies those who use it, and the former is that of which so many complaints have been made, and doubtless with justice, and which have given fodder corn a bad reputation with those farmers who had rather give heed to what they hear than try experiments for themselves.

**An active Farmers' Club** is that of Oxford, O., of which the Rev. James McGregor is President, and Miss Virginia Dare, Secretary. The meetings are held monthly, at the residences of the members, and the programmes for all the meetings of the year are neatly printed beforehand. The programme is not a mere statement of the topic, but gives a digest of sub-topics, and persons are appointed to speak upon these. The programme for this month will give an idea of this complete and excellent arrangement: "January 2, 1879. 10 A.M. The Club will meet at the residence of Mrs. E. S. B. Topic.—Wastes of the Farm and Household. Sub-Topics.—1. Waste Lands in Fence Rows; Sprouts; Washes; Knolls, etc. Opened by Mr.... 2. Wastes in Keeping and Management of Horses, Brood Mares, and Colts.... 3. Wastes in Keeping and Management of Cattle, Cows, and Calves.... 4. Wastes in Breeding, Feeding, and Management of Swine and Sheep.... 5. Wastes in Machinery, Bad Buying, and Poor Care.... 6. Wastes in Harvesting and Storing Crops, Corn, Grain, and Roots.... 7. Wastes in the Kitchen. Mrs. —, (this and the following are assigned to ladies).... 8. Wastes in Amount and Kinds of Food.... 9. Wastes in Heating and Cleaning the House.... 10. Wastes from Irregularity and Want of System." This club means business.

**Seedling Peaches.**—"P. S. T.," Spring Creek, Va. Has been told that seeds from budded peaches would not come up.—Which is nonsense. Has been told by others that the seeds would produce such fruit as the tree would have borne had it not been budded. This is another error. No one can foretell what kind of fruit a peach seed will produce, but it is more apt to have fruit like the tree which bore the seed than will other cultivated fruits. Some varieties of the peach reproduce themselves from the seed with great regularity; with others it varies, being either poorer or better than the parent tree. To be sure of the variety, we bud.

**Buying Tools.**—The winter is the time to buy tools. Every farmer should, at this season of the year, determine what implements he will need for the next year, and make arrangements for procuring them. If a moving machine is to be bought, let him take time by the forelock, and look into the merits of each kind of these machines, and buy intelligently; do not wait until the grass is ready to cut, and rush and buy the one nearest at hand. By sending to the various manufacturers, circulars with full directions, and illustrations, can be obtained, together with prices, etc. If a plow is needed, do all the work of selecting it, before the busy season is at hand, that it may not be "on the way," just when the best week for plowing is passing. In the peace of winter, prepare for the war of summer.

**Sewing Machines.**—The largest sewing machines now in use weigh 800 lbs., and are employed in carriage manufactories for doing the stitching of the leather, as upon the dasher and other parts. These large

machines are as perfect in their action as the small, family ones, and accomplish in a few minutes what would require hours to do by hand, and do it in a superior manner.

**The Vandal of Laurel Hill.**—At Laurel Hill Cemetery, in, or near, Philadelphia, there were two Cedars of Lebanon, each some 50 feet high, and well known to lovers of trees as among the finest specimens of this Cedar in the country. We learn from a late "Gardener's Monthly" that one of these trees were cut down! And why? Because the tree was in the way; it interfered with the reading of the inscription on some paltry grave-stone or monument! We say "paltry," with no reference to the particular handful of dust that the stone may for a few years mark, but any monument whatever, by the side of such a tree, is a miserably paltry affair. A few dollars and a few day's work may restore a gravestone or a monument—whatever lettering there may be, of no possible use to the dead, and only flattering the vanity of the living who put it there—could be easily replaced. But that tree! The miserable marble tbing of to-day would sink into utter insignificance before any tree 50 feet in height—but before a Cedar of Lebanon of 50 feet, before any Cedar of Lebanon, how miserable paltry seems any work of man. It is well to be charitable, and assume, difficult as it may be, that this person knew no better. Could he have known that the very ancestors of this tree are now regarded as among "the most renowned natural monuments of the universe;" that they furnished Solomon wood for the Temple; that this very tree descended from those mentioned all through Sacred History; had he known that to this day even the Arabs hold the ancestors of this tree as sacred, could he have cut down a Cedar of Lebanon, as if it were a used up telegraph pole? This tree would, no doubt, live for centuries after the elements had obliterated the letters chiselled into the slab or monument, centuries after the miserable piece of carbonate of lime had crumbled away, centuries after the memory of the dead whose monument was to be preserved, and centuries after the memory of the preserver of the monument had passed away, would this Cedar of Lebanon have stood, and been an object of interest and admiration—but it was in the way of somebody's head-stone, and was cut down!

**Fresh Air for Fowls.**—In protecting poultry from the cold, do not shut them up so closely that they can not get a sufficient amount of pure air. Ventilate the fowl house, otherwise the fowls will sicken. Feed well, and in winter mornings give a warm mess.

**Farmer's Clubs** are now holding their meetings in various parts of the country, and if properly conducted, much information can be thus exchanged. The social aspect of these gatherings is not to be overlooked, in estimating the good such gatherings do. At best, the farmer's life is a secluded one, but not therefore to be considered dull and monotonous. Farmer's Clubs tend to make good neighbors, in more than one sense.

**The Importation of Plants.**—Whoever has been so unfortunate as to have a friend abroad send him a present of a box of living plants, will, after his experience, be ready to join the free-traders and declare against all duties, so far as plants go. We find that the dealers in plants are also desirous that the duty be abolished. To them the importation of plants is like the importation of raw material; they only get from abroad a stock from which to propagate, and the case is exactly parallel to an import on the crude stuff in manufactures, the raw-material of which is not, and can not be, produced at home. But aside from this, the delays, which in the routine of the Custom House seems to be unavoidable, are such that it plants reach the port in fair condition, the time that must elapse before the owner can get possession of them is the death of a large percentage. A ridiculous feature in the law is, the duty on common roots is 20 per cent., while if the plant is unfortunate enough to have a bulb at the base, Uncle Sam wants 30 per cent. If our beloved Uncle will make this nice distinction in the duty, he should have officers who can make the distinction in the plants themselves. A friend of ours recently had a box come over, which in the routine of the Custom House was appraised and the plants therein were appraised as bulbs; none of the plants therein had bulbs any more than a cabbage has, but the United States Government, through its sworn officers, said they were bulbs. It now becomes a delicate question; if these plants, which the highest authority have pronounced to be bulbs, should grow and still produce common roots, are they not guilty of constructive treason, and is not our friend an aider and abettor? Why not he done with at least this much of nonsense. If plants are to pay a duty why not have it uniform-alike for all; this would avoid the overhauling of the plants by persons who do not know a bulb from "a permanently abbreviated, tunicated, subterranean stem". Duties on plants are a serious drawback to horticulture, and help only foreign growers.

**The Food Supply of England.**—A correspondent, "J. B. C.," in N. S. Wales, criticises an article, published in Sept. last, in which we suggest that England must in future draw largely upon this country, for her supplies of grain and meat, and that in this trade, we are likely to be without competition. He thinks that were we to give up grain growing, and take to grazing, we might successfully compete with the English farmers in meat, but he suggests that in wheat the Australian colonies are about to enter the field as competitors. He says: "For wheat growing, we have the soil and climate, and we only require to take advantage of these two grand helps. This we seriously expect to grapple with, on a more extended scale ere long." In the matter of meat supply, he is equally confident, and says that next month they will send their first shipment, protected by some one's "process," and "hopes for great success." In our article, we had in view European competition. Our Australian friend's wheat, according to his letter, is yet to be raised, and his meat is yet to be shipped. When these reach the market, if the American farmer can not successfully compete with the Australian in meat and wheat, he (the American) will do something else. In the meanwhile, we shall remember a homely proverb—"Its the longest pole that knocks down the persimmons."

**Osage Orange Hedge.**—"T. D. H." Russell Co., Va. The Osage Orange is almost universally raised from seed. Plants may be grown from cuttings, but at a vastly greater expense, and not be so good as seedlings. The seed is not usually on sale until February and March. This is to be sown and the plants grown the first year in a seed-bed, never in the place where the hedge is to stand. Seed is sown as soon as spring is fairly opened, it being first sprouted by keeping it moist in a warm place for a few days. Hedge plants one-year-old can be had at a very low rate; by purchasing these, a year will be gained in the growth of the hedge, and all trouble of seed-sowing and future care of young seedlings avoided. Your other questions are answered in Notes About Work.

**A Submerged Pump.**—Theoretically a pump should raise water by atmospheric pressure, ("suction" as it is often called), for about 33 feet. But owing to imperfections in our pumps, it is rarely that they can be depended upon to raise water directly, for over 25 feet. As the majority of wells are of a greater depth than this, numerous devices have been resorted to in the construction of deep-well pumps. One of the most efficient pumps of this kind is a force-pump, placed completely under water, where there is no appreciable loss from the leakage of air or water. By an ingenious contrivance of levers, the motion is imparted to the pumps placed below the surface of the water, and it gives a full and continuous stream, thrown with great force. We had one of these pumps in use for several years, during which time it kept in perfect order, and worked to our entire satisfaction; its use was only discontinued on account of being obliged to abandon the well. The fact that the American Submerged Pump, the kind to which we have reference, can not freeze is not a small point in its favor.

#### Further Household Notes.—(See p. 23, etc.)

**Short Notes on Air.**—At the freezing point, water is 770 times heavier than air; but heat expands air, making it lighter, so that at a temperature of 60° it is 815 times lighter than water.... At the medium temperature of 60°, with a barometric pressure of 30, every 100 cubic inches of air weigh about 31 grains, and every 13 cubic feet of it weigh a pound. The air in a room 20 feet square and 10 feet high, weighs 306 lbs. avoirdupois, and a 31-gallon barrel full weighs just about 5 ounces.... From the freezing point (32°) air expands  $\frac{1}{493}$  of its bulk for every degree of added heat shown by the thermometer.... At the surface of the earth, the pressure of all the air above is equal to about  $14\frac{1}{2}$  lbs. upon every square inch, or 2,105 lbs. upon every square foot (over a ton!).... Higher up there is less pressure of its own weight, and it is expanded or rarified, so that at the height of about 2½ miles (2.7) it is only half as dense as at the earth's surface, and it takes 26 cubic feet to weigh 1 lb. At the height of 5½ miles, it has only one-fourth of its density at the earth's surface, and 52 cubic feet weigh only a pound.... The pressure of the air upon water at the earth's surface is so great that it only boils when heated up to 212°. But as the pressure higher up is less, water boils at 1° less of heat for about every 550 feet we ascend. At  $\frac{1}{2}$  mile high, water boils at 207°; one mile high at 202°; two miles high at 193°; three miles high at 183°, and at this temperature the boiling water is hardly hot enough to cook potatoes. The air grows less and less dense until at about 45 miles high there ceases to be any air at all, it is supposed—only vacant space.... An important property of air is that as it becomes warmer it absorbs water or vapor of water, and *hides it within itself*, so to speak; as it cools it gives out this water again. The air in a room 20 feet square and 10 feet high, when heated from 32° to

only the temperate heat of 70°, secretes within itself  $3\frac{1}{2}$  pints of water. A current of warm air when cooled by any means, as by meeting a current of cold air, gives out its secreted moisture; the little water atoms given out become visible in the form of clouds, and when there is much water thus let loose the little drops keep uniting until so heavy as to fall down as rain. So the warm air gathers up from the earth's surface myriads of watery particles, carries them heavenward hidden unseen in its vast storehouse, until it chancs to be cooled, and then it drops the particles back in rain—or in snow if it is cold enough to freeze the falling drops.

**Dampen the Air Now.**—We can hardly too often suggest the importance of providing ample moisture in all rooms heated by stoves, furnaces, steam pipes, or hot water pipes. There are sound scientific reasons for this, as well as in the results of practical experience. As stated in "Short Notes on Air" above, every degree of heat added to the atmosphere in a room gives it a power of absorbing and secreting moisture. The air in a room 20 by 20 feet and 10 feet high, at 32°, holds, secretes, about  $1\frac{1}{2}$  pints of water. The same air heated to 70°, secretes upwards of two quarts of water, and unless this is supplied, it is hungry for more water, absorbs it from every accessible source, from the furniture, from our bodies, and especially from the breathing organs—the mouth, throat, and lungs, leaving them dry and husky. Therefore, every time the air in the room is changed by the admission of fresh, cold air, and heated to 70°, two quarts of water should be evaporated into the room. The strong objections some have to warm-air heaters have arisen mainly from this cause. In using furnace heaters we always put into the hot-air chamber extra water-pans besides any that are supplied by the manufacturers, and take good care to always have them filled with water. In stove-heated rooms there should usually be an evaporating surface of water equal to one square foot for every 12 feet square of flooring, and more if the water is not on a hot place enough to keep it rapidly evaporating. Plants in a room are mainly destroyed, or have a sickly growth, because the warm air becomes too dry and sucks out the very juices of the plants. The "house plants"—"olive" or otherwise—suffer similarly. In a warm room, a large towel frequently wet and wrung so as not to drip, and hung over a rack or chair back near the stove, will make a marked difference in the comfortable feeling of the atmosphere and in its healthfulness.

**Macaroni—Vermicelli—Sea-Biscuit—Pilot Bread—Plain Crackers, and Common Bread.** are all about alike, in composition and nutriment. Macaroni and vermicelli differ only in the size of the tubes, both being made alike, and both are simply dried dough made of flour and water only, the same as pilot or sea-bread and plain crackers. The wheat grown in southern Europe contains more gluten and less starch than any other, and therefore makes better macaroni. This gluten is nitrogenous, like lean meat, casein or curd of milk (cheese), etc., and strengthens one's muscles more than the more starchy northern flour. Starch is carbonaceous, supplying material for producing fat and for promoting warmth in the system. Millions of people in Italy use macaroni as their chief, if not sole food the year round—the gluten answering for the lean meat consumed by other people to produce muscular strength or working power. Sea-biscuit, Pilot bread, and plain crackers, those without the "shortening" of butter or lard, are simply flour and water, worked into tough dough and baked instead of being air or sun-dried as macaroni and vermicelli are. They are usually made of northern grown wheat, containing more starch and less gluten than macaroni.

**A Nice, Light, Toast Lunch.**—It often happens that after a late heavy dinner, or when arriving home late in the evening, or when one is an invalid, or dyspeptic, and especially when a troublesome tooth or other mouth ailment prevents proper mastication of harder food, one wants a light, easily digestible and easily masticated dish or lunch. Well-cooked oatmeal, the grains nearly whole and not "all in a mush," is quite good, but is not always accessible, and is not liked by all. Lately we have found the following very good, especially for a late supper or lunch, eaten only an hour or two before retiring: Toast some slices of bread pretty well, scraping off any blackened, charred portion; lay the slices on a plate, preferably a soup-plate, and pour on cold milk enough to wet it through, and leave half an inch or so in depth of milk in the plate. Good milk; a little extra cream in it is all the better, and a very trifle of salt improves it for our taste. Put over the toast thus prepared an inverted large earthen bowl, or tin basin, large enough to cover it and set down upon the plate all round. Put this in a warm, not very hot, stove oven, two, three, or more hours in advance. The milk will cook and evaporate—and its substance be condensed in the toast, while the cover will keep the toast moist. It is

then very good, and eats well without butter, though a little may be applied if desired.

**Speaking of Toast.** comparatively few know what really good toast is. A hasty singe of one or both sides does not make toast; nor do thin slices of bread dried through. Cut slices of uniform thickness, a plump half inch or  $\frac{3}{4}$ ths inch; move around over a brisk fire, to have all parts toasted alike; keep only so near the coals that the pieces will be heated through when both sides are well browned. If the slightest point is blackened or charred, scrape it off, or it will spoil the flavor of the whole. If covered with an earthen bowl, it will keep both warm and moist. A clean towel or napkin will answer if it is to go at once to the table. But, nobody can make good toast out of poor bread. Stale bread may be used for milk-toast; sour bread may be improved by toasting it through; heavy bread makes poor toast. Sweet, light bread, only a day old, or less, makes the best toast. For older bread and scraps see the next item.

**"Rusk,"** was the old farm name for what is a palatable preparation of stale and dry bread. Save all pieces of dry bread, loaves too dry to be longer palatable, crusts, etc. Put all together, first carefully sorting any mouldy bits, and any burnt crusts. Bake or dry thoroughly in an oven until well browned—not dark-brown or coal blackened, a dark-buff-brown is best. This will keep a good while. When wanted for use, crush finely with a rolling-pin or otherwise. To be eaten in milk, of which it will absorb a large quantity. It is not only a nourishing dish, but makes a good disposition of much dry and stale bread that would otherwise be wasted.

**A Good Soft Ginger Cake.**—Take 1 cup of Molasses; half cup of Butter or Drippings, 1 cup boiling Water; 1 teaspoonful of Cooking Soda; and half teaspoonful of good ground Ginger. Mix soft, bake quickly.

**To Fry Fresh Fish,** so as not to absorb the fat, or destroy the delicate flavor of the fish, is quite a desideratum. A Lady who has attended Miss Corson's practical Cooking Lectures, contributes the following to the *American Agriculturist*—derived partly from Miss C's advice, and partly from her own experience. Small fish are to be fried whole; large fish have the fleshy portions cut off with a very sharp knife, and divided into strips (fillets) of a convenient size for serving. When cleaned and ready for cooking, wipe dry, and roll them in powdered cracker or bread crumbs. (Cracker, ready pulverized, is now sold at most grocery stores, under the name of "cracker dust.") Dip the fish, or pieces, in well-beaten egg, and again roll them in the cracker dust or crumbs, removing any lumps so as to leave the surface smooth. Have the fat hot, and drop in the pieces, watching them carefully until they cook to a golden brown; then lift from the fat and lay upon thick paper to absorb the fat. Fillets of fish with the bones in, may be treated in the same way. By this method the fish are well flavored and much more digestible for weak stomachs. Fish are nourishing, and not only supply good food for the muscles, but also furnish good brain material.

**Oysters and Clams, and Meat Croquettes** (balls or cakes) are best fried as above described for fish. The egg and cracker or crumbs retain their flavor, and keep out the frying fat. Placing on brown paper to remove the surplus fat is an important part of the process.

**Putty in Tasmania.**—There is no part of its world-wide domain in which the *American Agriculturist* meets with more appreciation than in Tasmania and Australia. In return for the many "Hints and Helps" we have given our Island friends, we are glad to occasionally receive some in return. A friend writes from Hobart Town, Tas., that having to reset some 18 squares of glass, he found the old putty, which had been in place for several years, very difficult to remove without injury to the sash. A fellow mechanic suggested the following method: "Take a heated iron, a soldering 'iron' (which is copper) is the handiest, and run it over the putty that fastens in the glass; in a few seconds it will be found that the putty, though before so hard as to require a sharp blow to take any effect upon it, will become so soft as to be removed with a common pocket knife."—Our far off friend says:—and we commend his saying to those near at hand as well as at a distance—"I often think that simple common things are not communicated as they should be, as persons mistakenly suppose that others know such matters as well as they do themselves."—The simplest devices are often the most useful.

**Delaware Co. Dairymen's Association** held its regular fair in Delhi, N.Y., Nov. 12—13. From the report sent us by the Secretary, together with the list of premiums awarded, it is evident that the show was a large and successful one.

### The Treatment of Manure in Winter.

How can a farmer make money? Only from large crops cheaply grown or from animal products cheaply procured. How can large crops be cheaply grown? Only by means of abundant manure and good cultivation; the one being unavailing without the other. Then it comes, after all, to this: that if a farmer would make money, the size and quality of his manure pile is the exact complement of his profits from his crops; and without manure he may hope in vain to make money. His first thoughts

and chief employment at this season must be directed to making a supply of manure for next year's crops. It is better late than never, and though it is now late, thousands of farmers who have not yet begun, may yet do something towards securing a stock of manure for use in the spring. One of the most important parts of the work is, to provide a proper receptacle for the manure. An open yard from which the water drains away in all directions is the poorest place for manure making; and yet in such a yard an excellent manure pit may be made. We had recently the opportunity of showing a neighbor how to make such a pit, which was done at little expense, at the side of his yard, and we now see him every day hauling load after load of stuff into the pit to make a rich compost. The yard sloped considerably on one side towards a road. A pit 20 feet in length was dug in this bank with the bottom sloping backwards, and somewhat lower at the rear than the front. The pit was 16 feet wide and 8 feet deep, at the rear end. A fence was made around it on the yard side with a set of bars, so that the contents of a cart could be tipped into the pit. The shape of the pit is shown in the engraving. The pit was half filled with leaves from the woods, sods, and muck from a swamp, coarse manure from the yards, sods from the road sides, which were plowed and cleared for this purpose, yielding a large quantity of material. Then the manure was thrown into the pit and the yard was furrowed so that the rain water which usually gathered in the center of it, should run into the pit and keep the manure moist. The pit was made in October and in about one month was nearly full. Before it was started the farmer thought it would be foolish to make it, as he could never fill it. But one can never know what he can do until he makes an attempt. There is yet time to do a great deal in this way before spring, and if nothing but leaves are raked up in the woods to make an absorbent foundation for the pit, much may be done with them. It is necessary to have a good layer of stuff in the bottom to hold all the moisture of the manure, and if there is danger of over-heating, water may be hauled and poured on to the heap, unless there is some more ready method of applying it.

#### A VALUABLE WORK.

### AMERICAN FISHERIES.

A HISTORY OF

### THE MENHADEN.

P. O. Drawer 12, Bridgeport, Conn., U. S. A.

## Iowa Barb Fence Co., Limited.

Marshalltown, Iowa.—Johnstown, Pa.—93 John St., New York.

Sole Manufacturers of Burnell's Patent Four-Pointed Steel-Barb Wire Fencing, Galvanized and Painted; Staples, Stretchers, Pincers, Wire Cutters, Post-Hole Diggers, Iron Posts, etc.

For Sale at all Hardware Stores. Ask to see it.

Illustrated Circulars and Samples sent by Mail to any part of the World.

Our Wire is put up on spools in lengths of about one hundred rods, weighing from 100 to 110 lbs.

One pound measures 15 feet in length; 352 lbs. measures a mile. Our staples run about 80 to the pound. Iron posts, weight, 12 lbs.; stretcher, 12 lbs.

Having just put up (in addition to our Marshalltown, Iowa, factory,) extensive works at Johnstown, Pa., in the very heart of the Iron and Steel industries of this country, we have facilities for turning out more Barb Wire than any other company in the United States. We manufacture under our own patents issued June 19th, 1877, and are ready, willing, and able to protect all dealers and consumers of our Barb Wire.

Our Wire is all manufactured from fresh ingots of Steel made direct from the ore (we use no scrap or old rail ends), and has a tensile strength of 2,000 pounds to each line of wire; it has a four-pointed barb which passes between the two wires, and then is wound around both, but not so tight as to bind the wires solid together, and destroy the contraction and expansion. Our four-pointed barb has a great advantage over those cut from solid metal: In that style, the twisting of the wire hard like a rope injures the strength, greatly increases the weight, and is liable, especially in cold weather, to break and untwist, allowing the barbs to fall out; of course, no two-pointed wire can at all compare with a four-pointed, particularly the kind where the barb is twisted around only one wire.

In regard to the construction of our Barb Wire Fencing, to counteract the effects of our severe climate, we claim to have, after much experimenting, found out the best manner of twisting wire together. When our wire is expanded by heat the twist simply loosens, and when contracted by cold tightens, all without altering the relative length of the combined wires. When we remember that a length of 100 feet of steel wire, in a cold winter day, is one inch shorter than in a hot summer day, we can readily understand how it is that so many single wire, and tight twisted double wire, fences, break, or pull the posts down in cold weather.

The saving in land surface in putting up the Barb Fence is a matter of great importance. For instance, the old-fashioned zigzag or worm fence takes from every hundred acres an area of five acres, and this strip of land is worse than wasted, as it becomes a jungle of noxious weeds and harbor for all kinds of animals and vermin that prey upon the crops. Of course the same waste of land and objections apply to a stone fence, and much more to a live or hedge fence, which usually occupies a strip of land ten to fifteen feet wide, exhausting the soil on either side; this mode of fencing is rapidly declining in this and foreign countries.

It is the cheapest fence made; the most durable; is not affected by fire, wind, or flood; does not cause snow-drifts; takes fewer fence posts; stock can not push it down; it protects itself—acts on the defensive; it takes but little room; you can cultivate close to it; weeds are easily kept out of it, requires but little labor to put it up; you can draw at one load enough to fence a farm; and can fence a good-sized farm in a day; it is the greatest practical invention of the age, and has come to be the farm and railroad fence of the country.

One Thousand Pounds of our Wire will make over

### A MILE

of Fence of three Lines.

A Good substantial Fence for Farms or Railroads can be put up for less than 50 cents a rod, including posts.

We ask the readers of this Paper to examine the cuts of the different Barb Wires, as illustrated by the Editors on another page, and judge for themselves which is the best. (Ours is No. 14.)

Address, IOWA BARB FENCE CO., at either  
Marshalltown, Iowa; or 93 John St., New York; or Johnstown, Pa.

## STOP The CRACKS! Shut out Cold Air Drafts.

The wintry winds driving through the crevices of shrunken doors and windows, or those not tightly fitted, may double the cost of fuel, produce constant discomfort, and very often result in colds and even fatal sickness. A few cents worth of simple **Rubber Weather Strip** applied to a window or door will stop the trouble and save in fuel many times its cost in one season. Such strips, in a new and convenient form are

**Now Readily Obtainable,  
Everywhere by Mail,  
and at Trifling Cost,**

and can be put on quickly by any one.

The New **"ECONOMY METALLIC WEATHER STRIP,"** is a folded sheet of India Rubber (fig. 1), its edges folding over upon a flexible metal strip, ready punctured for tacking on, and presenting a flexible, cushion-like, yielding surface covering the opening, so that it does not affect the free movement of the windows or doors. If desired it can be removed and packed away in small space during summer. Fifty

feet of it coils into a roll only  $\frac{1}{4}$  inch thick and 10 inches in diameter (fig. 2), and it can be sent anywhere by mail.

It costs only 4 cents a foot for Window size, and 5 cents a foot for Door size. Having tested its utility and convenience by a trial of it this winter, we have, for the convenience of the Readers of the *American Agriculturist*, arranged to supply any orders sent to this Office, for coils of 25 or 50 feet each, at **five cents per foot** for the Door Strip, or **four cents per foot** for the Window Strip. It will be sent by express unpaid, or be forwarded by Mail to any part of the United States on receipt of **half a cent per foot** extra for pre-payment of postage.

ORANGE JUDD CO., 245 Broadway, New York.

## HOW TO HAVE A CLEAR HEAD, AND Common Mind Troubles.

See Herald of Health for 1880. \$1.00 a year. Samples, 10 cents. See *Agriculturist* for full particulars. Address M. L. HOLBROOK, 13 & 15 Lighthouse St., New York.

Send 10 Cents for a Sample Copy of the  
**American Bee Journal,**  
The Oldest, Largest and Best Bee Paper.  
THOMAS G. NEWMAN & SON, CHICAGO.

**\$10,000.  
SAFETY  
LAMP.**

**AGENTS WANTED** and depth of your lamp.

#### PERIOD VI.

**National Churches and Denominations.** 1660—1878.

8vo. Pages 727. Price \$3.00.

Dr. Blackburn has written, we are bound to say, a very good History. It is no small feat to tell the whole story of the development of Christianity and the Church within the compass of about seven hundred octavo pages; but Dr. Blackburn has done it. What is more, he has succeeded in imparting to it no little picturesqueness of detail, so that his facts and figures are far from being too much for him, and his narrative in consequence dry reading. He is master of a vigorous style, and some of his thumb-nail portraits of the fathers, the school-men, the reformers, and the political leaders in conjunction with them, are as good as any thing of the kind we have ever seen. We commend the work to any body who would like, by means of a single book, and at a single reading, to refresh his mind as to the progress of eighteen Christian centuries.—*The Literary World.*

## HITCHCOCK & WALDEN, CINCINNATI, OHIO.

**A GOOD STORY** In fact, several of them, by the best writers, may be found in every number of our illustrated 16-page monthly, **HOURS AT HOME**, besides sketches, poetry, and short articles innumerable. Also articles on Fancy Needlework, Wax Flower-making, Chromo-Photography, etc. Only 50 cents a year, including a charming Chromo Head,  $\frac{1}{4}$  life size, of the handsomest woman of history. Sample copy and a pair of beautiful 6x8 Landscape Chromos, 7 cts., postpaid. Agents wanted. Stamps taken. Sample price to any person sending the addresses of ten of their neighbors. **J. L. PATTEN & CO., 47 Barclay Street, N. Y.**

We cheerfully credit it with being one of the best edited of our Western agricultural exchanges.—*Spirit of the Times*, N. Y.

**The American People Want It!**  
**The Canadian People Want It!**  
**The People of this Whole Continent Want It!**  
**Want What?—Andrews' Bazar!**

the best **Illustrated Fashion and Family Journal** published in the world, for the unprecedentedly low price of **One Dollar per annum**, a trifle over **EIGHT CENTS PER MONTH.**

**ANDREWS' BAZAR** gives the **Freshest Fashion News**, noting every varying freak of foreign modistes, and, with careful discrimination, so modifying the same as to meet the refined tastes of the ladies on this side of the water. **ANDREWS' BAZAR** devotes ample space by word and hint to **Home Dressmaking**, which alone make it invaluable to every mother in the land. **Lovers of Refined and Elevated Literature** will find in its columns an admirable banquet, chaste and carefully selected, the contributions of the most eminent writers of this and foreign countries. The monthly article, "Illustrated Needlework," presents a perfect compendium of practical information as to the manufacture of the most exquisite embroideries and laces, giving in each issue new designs so clearly explained that they can easily be reproduced. From **Paris, Berlin and London** able correspondents make monthly contributions to its columns. **Hygienic and Scientific Information** of sterling worth and importance is carefully collated from the best available sources. The "New York Trade Notes" of **ANDREWS' BAZAR** are an inside view of this the great market of the continent, and present an absolutely exact statement of what goods are desirable and what are not, with retail quotations compiled with care, thus making this journal indispensable to every merchant who desires to keep fully posted on all matters relating to his trade.

**The Little Folks** will find **ANDREWS' BAZAR** just the paper to meet their wants, containing, as it always does, fresh and original stories written expressly for them. "Turtle Tracks," our funny column, is always filled with *bon mots* of delicious flavor, and is extensively quoted by every journal in the land which caters to this growing taste of the American people. In short, **ANDREWS' BAZAR** occupies in journalism a field at once unique, practical, and entirely its own.

### SIX YEARS OLD!

Six years ago **ANDREWS' BAZAR** was launched upon the "sea of literature." Its superlative merits, recognized from the start, has placed it in the front rank above and far beyond any of its competitors. Six years ago unknown, and to-day to every post-office in the land it goes a welcomed visitant. Its proprietor, ambitious and unrelenting in his determination to make **ANDREWS' BAZAR** an absolute necessity to every lady on this continent, pledges himself to spare neither expense nor time to secure a constant succession of sparkling and brilliant surprises for his readers.

### A PRESENT TO EVERY SUBSCRIBER.

Every subscriber to **ANDREWS' BAZAR** for 1880, renewals and new subscribers alike, will be presented, free, with **Fifty Cents worth of ANDREWS' BAZAR PATTERNS**, which have just been awarded the Bronze Medal at the **CINCINNATI INDUSTRIAL EXPOSITION**, the highest award of the association over all competitors.

Everybody should subscribe in time to secure **THE MAGNIFICENT HOLIDAY NUMBER**, which will surpass anything of the kind ever placed before the people of this continent. It will be embellished with splendid illustrations appropriate to the season, and contain practical designs for Fancy Holiday Work, superb Christmas stories, and for the **LITTLE GIRLS** some elegantly illustrated patterns for **Dolls' Wardrobes**, consisting of Morning, Dinner, Evening, and Reception Costumes; also full sets of Dolls' Underclothing. Patterns of these can be furnished if desired.

### OUR GRAND CHRISTMAS GIFT!

Every Yearly Subscriber to **ANDREWS' BAZAR**, and those who subscribe before January 1st, 1880, will be presented, free, with a **Magnificent and Gigantic Supplement Sheet**, 33x46 inches in size, containing useful and practical illustrations of Fancy Letters and Monograms; Designs for making Laces, for Flannel Embroideries, and for Worsted Work; Painting on China; Silk and Satin, and a variety of Fancy Articles for Christmas Gifts, and each so clearly pictured that it can be cut from the sheet and used as a pattern without destroying any other. Any dealer would charge \$10 for these designs, which we present, free, as a **Grand Holiday Gift** to our **Yearly Subscribers**.

Those whose subscriptions expire with the November number should renew at once in order to receive this magnificent gift.

NOTE.—This sheet will not be given with sample copies of December number, being positively reserved for Yearly Subscribers.

Remember, the Subscription Price of **ANDREWS' BAZAR** is only **One Dollar per annum**, and every subscriber gets a present of **Fifty Cents worth of Patterns**.

Single copies, 10c. For sale by Newsdealers everywhere. Sample copies mailed to any address upon receipt of 10c.

**CANVASSERS** can make more money working for **ANDREWS' BAZAR** than for any dozen other papers published in America! Send a 3c. stamp for our Illustrated Hand-book and Premium List for 1880. Address,

**W. R. ANDREWS, Publisher,**  
**Tribune Building, New York, or 171 W. Fourth St., Cincinnati, O.**  
Please state in what paper you saw this advertisement.

### SPLENDID KANSAS LAND!

The beautiful and highly improved **Farm of 640 acres**, known as the "**REEDER FLOAT**," situated about two miles north of the city limits of Lawrence, Kansas, is offered for sale at low figures and on easy terms. This is probably as fine an opportunity for an investment as can be found in Eastern Kansas. The farm embraces a full section, chiefly "second bottom" land, with about 300 acres under cultivation, the balance pasture and timber. Its proximity to Lawrence City, with its social, religious, and educational advantages, with great facilities of railroad transportation, with an abundance of fine water, etc., gives it special advantages over many other localities, and particularly as a stock grazing farm. If desired, the land will be divided or exchanged for improved unincumbered property in the East. For particulars apply to **ANDREW TOSH & Co., Lawrence, Kansas**, or to the undersigned, at Easton, Pa. **WM. W. MARSH, GEO. M. REEDER, Executors, or REEDER & REEDER, Attorneys, Easton, Pa.**

### CALIFORNIA LANDS,

large or small tracts; homes or investments for sale by **McAFEE BROTHERS, 202 Sansome St., San Francisco, Cal.**

### Twenty Years of Inside Life in WALL STREET,

Or, Revelations of the Personal Experience of a Speculator.

[SUGGESTIVE.]

INCLUDING

*Sketches of the Leading Operators and Money Kings—The Great Rises and Panics—The Mysteries of the Rings, Pools, and Corners, and How Fortunes are Made and Lost on 'Change.*

By **HON. WM. WORTHINGTON FOWLER.**

FULLY ILLUSTRATED.

Some ten years ago Mr. Fowler published a Volume, giving Ten Years of Experience in Wall Street. The work received the highest encomiums, and met with a very large sale. This New Volume brings the Author's experience down to the present time, thereby presenting in detail all the leading facts and incidents which have transpired in Wall Street for twenty years' past. Mr. Fowler is a graduate of a New England College, was formerly a State Senator of Connecticut, is widely known as a journalist, and tells the story of his personal experience in a graphic, entertaining style.

12mo. CLOTH. PRICE, POST-PAID, \$2.00.

**ORANGE JUDD COMPANY,**  
245 BROADWAY, NEW YORK.

### FOR THE LITTLE GIRLS.

### The "ÆOLIA" Piano.

Here is one of the prettiest and most pleasing toys we ever have offered, and while little boys of course will be glad to have it, it is specially designed for the **Little Girls**, who wonder, sometimes, we are told, why we don't get up more things "for them and not for anybody else." It is a pretty little Toy Piano, called "**ÆOLIA**." It has 15 keys, is 16 inches long, 10 wide, and 4½ high; its tones are very pleasing, and it will delight the fortunate little one who becomes its owner. The engraving gives a good idea of this attractive and very cheap toy.

**Price, \$1.00; Expressage to be paid by the Receiver.**

Send for a Catalogue of all our Blocks, Toys, and Games—mailed **FREE** on application.

# THE BAKER GUNS.

We make the best double gun in the world for the money—choke-bore, rebounding locks, extension rib. Our \$35 gun has the best twist barrels, and the best material throughout. All guns sent on trial and guaranteed.  
Price—Best English Twist Barrels, \$35. Damascus steel, \$50 to \$200. Send stamp for Descriptive Circular.

Three-Barrel  
GUN.

Two Shot and  
One Rifle.

A new feature in the Gun line. It is light, compact; from 8 to 10 lbs. in weight. The Rifle is perfectly accurate. It has proved a great success for all kinds of shooting. An owner of this valuable gun cannot make a mistake and take the wrong one when he goes out for game. All guns shipped on trial and guaranteed. Price \$75 to \$250.

W. H. BAKER & CO., Syracuse, N. Y.

## NATIONAL WIRE MATTRESS.

No SAGGING OR ROLLING TO THE CENTER ON THIS BED.

This is the very best and most durable Spring Bed that money can buy. It never can sag, it will never rust in any climate; it can be taken apart and folded up to occupy but little space, and it is the only one getting its elasticity from wire-tempered Springs.

Delivered to any R. R. Station in the U. S. or Canada, free of charge, on receipt of \$10.00.  
Address NATIONAL WIRE MATTRESS CO., New Britain, Conn.

## Hay Cutters & Corn Shellers.

Two invaluable articles, superior to any in the market, at lowest prices. Send for circular and prices.  
A. B. COHU, 197 Water Street, New York.

PRONOUNCED  
the

**BEST PLOW MADE**

by the

Northern Ohio Fair of 1879,  
State Fair of New York of 1879,  
State Fair of Michigan of 1879,  
and by the

Paris Exposition of 1878

when it competed with 187 other  
PLOWs, and received the GRAND  
GOLD MEDAL for being the BEST  
general purpose Plow in the world—  
an honor never before conferred  
upon a Hand Plow.

Is the MOST EASILY ADJUSTED  
and MOST PERFECT SCOURING  
PLOW ever invented, and the thou-  
sands that are in satisfactory use  
all over the land demonstrate the  
fact that no other CHILLED PLOW  
manufactured is equal in EVERY  
RESPECT to the "GALE."

For Circulars and prices, address  
**GALE MANUFACTURING CO.**  
ALBION, MICH.

View of a heel calk from a Steel Center, Self-Sharpening Shoe, after being worn all winter.

**PATENT STEEL CENTER, SELF-SHARPENING HORSE AND MULE SHOES.**

A sample set will be sent to any address, except in the States of Minnesota and Wisconsin, on receipt of one dollar. Prices by keg on application.

### THE ADVANTAGE

of the Steel Center Self-Sharpening Shoe is that the calks are **always sharp**. A thin plate of steel is rolled inside of the soft iron bar from which the shoe is made. The soft iron in the calk partially wears away, leaving the sharp steel center, as shown in the cut. Address: SHOENBERGER & CO., Pittsburgh, Pa. Agents for the United States except the States of Minnesota and Wisconsin.

W. S. BLUNT'S

## Universal Force Pumps.

Secured by letters patent.

THESE PUMPS HAVE RECEIVED THE  
"MEDAL OF SUPERIORITY,"  
The highest award of the American Institute  
for 1878 over all competitors.

These pumps have enormous power, and are for the house or for out-door wells of any depth. They are constructed with special regard to strength, ease of working, and durability. They can be immediately changed from lift to force pumps, and the air chamber can be revolved, so as to allow the handle to work at any desired angle with the spout. Having close tops, they cannot be tampered with. Attention is called to our new elegant pattern **DEEP WELL non-freezing FIRE PUMP**. Also, Blunt's Sand Vacuum Chambers.—A complete protection against sand or gritty water in dug or driven wells, pits, mines, and rivers. For hand or steam pumps, all sizes, from 1½-inch to 4-inch suction pipe.

## PRACTICAL TAXIDERMY, AND HOME DECORATION;

TOGETHER WITH

General Information for Sportsmen.

BY

**JOSEPH H. BATTY,**

TAXIDERMIST FOR THE HAYDEN EXPEDITION, AND OTHER  
GOVERNMENT SURVEYS, AND MANY OF THE LEADING COL-  
LEGES AND MUSEUMS IN THE UNITED STATES. AUTHOR OF  
"HOW TO HUNT AND TRAP," ETC., ETC.

125 ILLUSTRATIONS.

JOSEPH H. BATTY, the author of this volume, has devoted sixteen years of active life to the work of collecting and preserving animals, birds, fishes, etc. He was the Official Taxidermist of the Northern Boundary Survey, and also of the United States Geological Survey, under Dr. Hayden—generally known as the Hayden Expedition. Mr. Batty has, likewise, been for many years Taxidermist for several of our leading Universities, Colleges, Museums, and Public Parks.

His work, entitled "How to Hunt and Trap," published some eighteen months since, has received the warmest encomiums from recognized authorities, and from both the American and the European press. We anticipate a still more flattering reception for this volume, which is the result of long experience and practice, and conveys a vast amount of information on the subjects treated, not hitherto embodied in book form. There is no similar work in existence. While Coues and Maynard have devoted some space in their writings to Taxidermy, they have merely touched upon branches which are fully treated in this book.

The appreciation and love of "Home Decoration" increase with the growing taste and culture of the American people. Our author's chapters upon this subject are very timely, and will be keenly appreciated, especially by ladies.

In his Preface, the author says:—The mere skinning and stuffing of a specimen is but a small portion of the Taxidermist's real work or pleasure. The hand must be turned to the making of cases, and the eye trained to the blending of colors. Taste must be cultivated and exhibited in modeling and molding, and Nature's beauties should be imitated as closely as possible. Artificial rocks can be made to look as natural as the moss-grown specimens in the woods, and trees can be formed as graceful as those in their native forests. With the growing fondness for Taxidermy, many ladies are endeavoring to master the art, and in the variety of work necessary to perfect it, feminine taste and skill can be brought effectively into play. The collector can learn to mount his own specimens, the schoolboy his game, and in the general household, a buck's head in the dining-room, or a bright oriole in the parlor, presents a pleasing contrast to other ornaments.

PRICE, POST-PAID, \$1.50.

ORANGE JUDD COMPANY,

**AN ANTONIUS STRADIVARIUS VIOLIN, (Model of Anno 1731.)**  
**\$3. Violin Case, \$3. Snakewood Bow, and 600 Pieces Choice Selected Music.**  
 (Sent C. O. D. with Privilege of Examination.)

**ONLY \$10.00**

I have in stock a few VERY choice Violins of the above make that I think have had the misfortune—owing to a brainless Violin dealer—to have been “modernized,” namely, repolished. The renovation has made them, without any exception the most beautiful Violins we ever saw. These Violins have always been famous for their artistic model and graceful outlines and as the repolishing has served to bring out all the rich elegance of the wood, shadings from almost black to a rich chestnut hue, words are inadequate to describe the **Masterpiece of Art** they present. The Bow was designed expressly for this offer, is 29 inches long, of Snakewood which is noted for beauty and strength. The wood is a dark chestnut, mottled with irregular spots of black, making a rich contrast to its **Silver Bullion** windings. **White Ivory Frog** inlaid with **Mother of Pearl**, and **German Silver** trimmings, which makes it a perfect **Soloist's Bow**. The cut of the **\$3.00 Wooden Violin Case** is from a Photograph, showing the case exactly as it is. Remember I send C. O. D. with privilege of examination, so you can see just what you are buying. Address **CHARLES W. STORY, 26 CENTRAL ST., BOSTON, MASS.**

[TRADE MARK.]

## Veterinary Cosmoline

Is a heavy oleaginous hydro carbon of the consistency of an ointment, derived exclusively from petroleum. It is absolutely free from acids, alkalis, or moisture. When applied to wounded and inflamed flesh, it is a perfect protection against atmospheric action, flies, insects, animalcules, preventing the generation of microscopic organisms, and allowing nature absolute freedom to heal itself rapidly by a healthy granulation without scars. Never has there been a veterinary ointment that would heal so rapidly all the wounds, sores, and surface diseases of horses, cows, sheep, poultry, etc. For sale by Druggists. Price 75c. in 1b. cans. Descriptive circulars mailed in answer to postal cards.

### SUBSCRIPTION TERMS.

(English and German Edition at same Rates.)

For One or Two Subscriptions, One Year, the price will hereafter be (post-free) **\$1.50** each, instead of \$1.60.

[ALL POST FREE.]

Three Subscribers one year.....\$4, or **\$1.33** each.  
 Four Subscribers one year.....\$5, or **\$1.25** each.  
 Five Subscribers one year.....\$6, or **\$1.20** each.  
 Six Subscribers one year.....\$7, or **\$1.17** each.  
 Seven Subscribers one year.....\$8, or **\$1.14** each.  
 Eight Subscribers one year.....\$9, or **\$1.12** each.

Ten or more Subscribers, post-free,  
 Only **\$1** each.

[A free copy to sender of club of 20 at \$1 each.]

Single Numbers sent, postpaid, for 15 cents each. Specimen numbers for examination sent, postpaid, for 10 cents each. Subscriptions can begin at any time.

The Above Terms are for the United States and Territories, and British America. Add 14 cents extra per year for papers sent outside of the United States and British America, except to British Honduras. For the last named country the extra charge is 38 cts. per year, to cover extra postage, and Single Numbers, 17 cents, post-paid. Remittances, payable to Order of Orange Judd Company, may be sent in form of Checks or Drafts on N. Y. City Banks or Bankers; or P. O. Money Orders; or in Registered Letters, such letters to have the money enclosed in the presence of the Postmaster, and his receipt taken for it, and the postage and registering to be put on in stamps. Money remitted in any one of the above three methods is safe against loss. Bound Volumes from Vol. 16 to 38 inclusive, supplied at \$2 each, or \$2.30 if to be sent by mail. Sets of numbers sent to the office will be bound in our regular style for 75 cents (30 cents extra if to be returned by mail). Missing numbers in such volumes supplied at 10 cents each. Any Numbers of the paper issued for 23 years past, sent post paid for 15 cents each; or any full year, sent unbound, for \$1.50. Clubs of Subscribers can be increased at any time, at the club rates, if new members begin at same date as the original club.

NEW SERIES—No. 397.

IN THE SNOW. — Engraved for the American Agriculturist.

This picture is from a noted steel engraving, which we hardly need say is European, as every detail of wagon, horses, and men assert the scene to be foreign—all except the snow, that has a home-like look, hut snow storms are much alike wherever they occur. Still there is a difference in snow and snow storms. Those large light flakes that float leisurely downward, "as if the celestial geese were being plucked"—the apt simile of some one—those fluffy, pretentious flakes make a great show, hut they do not make the great snows; they indicate dampness and foretell a not very distant cessation of the fall. It is the little glistening scales, so fine that they make but little show in the air, that "mean business;" it is those that when they are sifting down so dry as to fairly rattle one another

as they seek out every crevice and pack closely, that come with our serious storms—those of the kind always called "old fashioned," though we never hear of a "new fashioned" snow storm. To be snow-heleagued if not lost in the snow, is an experience more pleasant to look back upon, than in its immediate enjoyment. What a desolate blankness spreads in every direction. There was no evidence of human existence to cover up except a trail that marked the course; unbroken, trackless whiteness everywhere. No food for horses, very little food for men, two hundred miles to the nearest known help! It does not require many inches of snow in a roadless country to make wagons useless as vehicles of locomotion. Snow storms there away at the present day defy the iron

horse—even four of them tandem, and what could our poor, jaded, skeleton horses do? Like the horses in the picture, they gave it up, and looked at us with a dazed expression, as if to say—"Well! what next?" How beautiful these dry snows are! What an illustration of the power of accumulation. Each tiny flake so insignificant in size, yet combined, they defy the most powerful engines. How exquisite their forms, and how varied! Not an angle since the first snow flake fell until now but measures exactly 60° or its equivalent. Then to think that this exquisite sculpturing is repeated times as far beyond our comprehension as are the distances of the farthest stars. "But did you think of all this when snowed in?" Oh, no! we took an account of our salt pork and hard-tack.

## AMERICAN AGRICULTURIST.

NEW YORK, FEBRUARY, 1880.

## Hints for the Work of the Month.

[The Hints and Suggestions in these columns are never copied from previous years, but are freshly prepared for every month, from the latest experience and observations, by practical men in each department.]

The Last Month of Winter has begun for the Northern farmer, while in the Southern States spring has already opened; whatever is to be done in the way of preparation can be no longer delayed. A late beginning makes a late season, and to regain time lost now, may be found impossible hereafter. A farmer who is behindhand is a prey to accidents and misfortunes of the season, and often finds his labor increased, and the results lessened by reason of his own carelessness. On the other hand, the forward man gets the benefit of every advantage, and many disadvantages of season are safely passed over, because he is ahead of them.

**Hauling out Manure.**—While the ground is hard or covered with snow, the manure heaps can be hauled to the fields with the least trouble. Those who have profited by our hints for the past few months, will have the manure in good condition for hauling out now; others will have it lying around loose and frozen, and consequently useless for some time yet.

**The Finest Manure** is made by turning the heap over twice. To do this, begin at each end of the pile, and throw off the manure to a distance of three feet, building up the new heaps, and placing the coarsest manure in the center. Then proceed until two heaps are made. These will soon heat, and a month or so afterwards the process may be reversed and the two heaps made into one again.

**Cabbages.**—Every farmer should raise cabbages, both early and late. For early kinds, the seeds should be sown in a hot-bed this month, unless plants started last fall have been kept through the winter in cold-frames. Directions for making a hot-bed will be found under the Notes for Kitchen and Market Garden. It is not a waste of manure to use it for a hot-bed, as it will be all the better for application in the garden after it has served this purpose.

**Spring Oats.**—In the South, if spring oats have not already been sown, they will require immediate attention. Not having time to tiller, like winter oats, 2½ to 3 bushels of seed per acre will be needed. A late sowing may yield an early harvest, by the help of a liberal fertilizing with a good artificial manure.

**Early Planting** is advisable for cotton, corn, and corn-fodder. For these crops, the ground should be in course of preparation this month, that advantage may be taken of good weather for planting so soon as it comes next month.

**Spring Wheat.**—In many localities spring wheat will succeed if it is sown early. Open weather this month, may permit plowing and sowing, although the under soil is still frozen. A cold spell may freeze the ground, or cover it with snow, but the seed is safe, the work is done; and one may rest contented, while others are grumbling.

**Plowing should be done**, only when the soil will crumble loosely; when the plow smears the up-turned surface, the soil will be injured. While earliness and forehandedness are commendable, one should make haste with caution.

**Look Ahead!**—A farmer should always think in advance of his work. The whole plan must be laid out in the head, before the hands are put to it. There is time yet left for thinking over what should be done in the next two or three busy months.

**Grass in the South.**—A great need in the South is grass for early grazing and hay. Some of the native grasses that have been fought and struggled with for years as weeds are now found to be of great value. By smoothing off a piece of grassy land, and using some fertilizer and encouraging the growth, a home supply of hay may be secured. It is often the case that a treasure may lie neglected under our feet, and some of the Southern grasses, long neglected, can be turned to profitable use.

**Grass in the North** is not made as available as it might. An opinion prevails that grass lands can not be kept in permanently good condition. Yet there are in many localities plots and tracts of grass that are very old and show no signs of failure. What has been done once in this way can be done again. A permanent pasture or meadow is invaluable. Why can not we try to make and keep them? This is a subject worthy the most careful study.

**Why can not we Grow Larger Crops?**—There are localities where it may pay to grow small crops cheaply, where one may skin the land for a few years and leave it, just as in some places cattle are or have been killed for their hides and the carcasses left to decay. But every year these localities are growing more and more distant in the West, and in time land will be too valuable to be used in so wasteful a manner. In central and eastern localities the future prosperity of the farmers will depend upon the growth of larger crops by the expenditure of more labor on the land. To reach this end will be a work of time, but it will never be reached unless a beginning is made, and there was never a more propitious time to begin than now.

**Values are Increasing.**—Every relic of the long continued depression—the seven lean years—now happily gone by, is passing away. Prices are advancing, and every purchased thing costs considerably more than a year ago. The farmer who values his land and stock may justly put up the figures from 25 to 50 per cent. His income must be made to increase in proportion, and this must be done to a great extent by increasing in every possible way the productive value of his property.

**Better Stock Must be Kept.**—The right stock too must be kept in the right place. The choice and management of animals require an accurate knowledge which must come from outside of his own farm practice. A farmer can not test these things for himself and run the risk of losses that would be ruinous to him. All this has been done and recorded in books and agricultural papers, together with much other indispensable information, so that

**A Farmer Must be a Reading Man;** else he can never hope to be as successful as he should be. A DOZEN VOLUMES OF THE *American Agriculturist* WILL FORM A NEARLY COMPLETE CYCLOPEDIA of agricultural, mechanical, and other useful knowledge for any one who lives by cultivating the soil. The work of the farm, garden, and household has been discussed, described, and explained in these volumes for more than 30 years back, in a full, fresh, and instructive manner; with them one can learn how to improve his own stock or where to procure

the best animals, as well as to improve every method of working, enabling him to meet nearly every question and demand that may naturally arise.

**Keep the Good Calves.**—As the cows come in, the best of the heifers may be selected for raising. There can be no better way to improve the stock of cows than to use a good bull and keep the best calves, well feeding and caring for them until matured. After these become cows a selection can again be made for breeding, and only the best retained. In a few years the value of dairy cows may be doubled by this careful practice of selection.

**Feeding and Care of Stock.**—On this subject there is nothing to add to the hints given last month. Prof. Atwater's articles on feeding (see page 61) should be studied until they are well understood.

**Vermin.**—The poultry house, if closely examined, may be found to swarm with lice. A gray mealy powder may be seen on the roosts, in crevices, and in the corners and joints of the building. Take a common squirt can filled with kerosene oil and inject the oil into every crevice about the house. Repeat this process if it is found necessary, and very soon the fowls will be free from these insect pests.

**Young Chickens.**—Early chickens which can be reared easily if proper care is given, may be kept in a glass covered coop protected at night by covering with straw. If severe cold is feared, heat a couple of bricks hot in the oven, wrap them in a piece of carpet, and put them in the coop. A large can or jug of hot water is also a very good warmer.

**Fowls** will need the best food if eggs are desired. Wheat steeped in boiling water, and given hot, and hot baked potatoes crushed with a masher, are as good food as can be given; water slightly warmed with a small quantity of Sulphate of Iron (copperas) in it, will be useful. Allspice mixed with corn-meal mush is an excellent condiment, and by no means costly. Laudanum in 10 drop doses has been found a remedy for the cholera, or poultry intestinal fever, which has destroyed so many flocks.

**Geese and Ducks.**—These are profitable birds in some cases, and may be kept where there is cheap grazing. Half a dozen geese will soon fill a good sized feather bed or a pair of pillows. The white ducks are perhaps equally useful in this way. Both of these will now begin to lay, but must be closely watched and kept up at nights or they will drop their eggs abroad. The eggs should be gathered and kept in a cool but not cold place until they are wanted for setting. A house suitable for geese or ducks is illustrated and described on page 60.

### Notes on Orchard and Garden Work.

In the Northern Atlantic States the winter up to the beginning of the year has been an exceptionally mild one, though some localities have experienced the severity of which European gardeners and orchardists are complaining. It would be better if we could have the weather continuously so cold that all vegetation would remain dormant, but that is beyond our control, and we can do but little to avoid or repair the damage caused by unseasonable prolonged mild weather, followed by severe cold. With the majority of hardy trees and shrubs, it makes but little difference how severe the winter, provided the cold comes on when vegetation is thoroughly dormant, but when a mild spell is succeeded by a sudden cold snap, the effects are most disastrous, especially upon the more excitable trees, such as peaches and cherries. When this occurs, and the blossom buds are fairly injured, nothing can be done to remedy the damage, and the best that one can do is to grow well formed trees during the coming season, in the hope that another winter may deal more kindly with them. To many of our readers spring begins with February, and it is everywhere proverbially the "short month," hence the plans for the year should be fixed upon by this time, and the tools, seeds, plants, etc., should be ordered, that they may be on hand when wanted. Manure is an important matter to every cultivator, and none should go to waste for lack of sufficient absorbents, such as muck, leaves, cut litter, etc. Many who write us for information might find an answer to their queries did they look over the Notes in for-

mer volumes, and given more in full than is practicable in an answer by letter. Of course this refers to those who have been our readers for some years.

### Orchard and Nursery.

**Renovating old Orchards** is an important work at this season, and was treated somewhat at length in the January Notes, to which we refer the reader.

**Grafting.**—If old trees produce poor or even indifferent fruit, and they are still sound and vigorous, they may be made productive and valuable by grafting good sorts upon them. This work should be done just as the buds begin to swell. If the tree is a large one, only a portion of it should be grafted the first season, beginning with the central part of the head. Great care should be taken that the grafts are of an excellent variety. It is a common notion among those who do not think about the matter, that the mere operation of grafting somehow benefits the tree. The grafted tree is in fact a new tree, all of the bearing parts of the old tree are cut away, and a new head is planted, so to speak, upon the old one. Hence the new top or head will be of the kind that is placed there, and unless good kinds are selected, grafting will be useless.

**Grafting** is planting a cutting in another tree instead of in the soil. When we plant a cutting in the soil, it forms roots of its own, and the tree will be all of one kind. When we graft, the cutting unites with a tree already having roots, and the top, which grows from the tree, will be of one kind, and the lower part of the tree will be of another.

**Who can Graft?**—There are men who go about the country doing grafting, some are very excellent and others are bunglers, but there is no need of employing any one. Any boy who can make a willow whistle can learn to graft, and every boy should be able to do it. We gave a full account of several kinds of grafting in May, 1869, and of other kinds in April, 1877, which numbers may be referred to. To answer a number of inquiries, we give here a few brief directions for *cleft grafting*, which is the easiest kind of grafting, and the one most generally practised, though it is by no means the best.

**Getting Ready.**—If cions are not already cut, lose no time in getting them. They may be bought at most nurseries. If you cut them yourself, be sure that the tree from which they are taken is of the right kind. Cut twigs of last season's growth only, a foot or less long; if cutting more than one kind, tie up one sort and mark it before beginning with another. Tie the cions in bundles, with their lower ends even, attach a label to them, or cut numbers on one of the cions in the parcel, to correspond with a list, lay them in a box, with damp sawdust or damp moss all around and over them, and keep in a cool place until wanted. If sawdust or moss is not at hand, set the cion in a box of slightly damp earth, covering their lower ends, well.

**Implements.**—A fine saw will be needed; a regular pruning saw is best, but any other will answer if it has rather fine teeth with a wide set. Two good knives, one very strong and heavy, the other smaller, and made and kept very sharp. A hardwood wedge made of a stick of hickory about 6 inches long and half an inch or so thick; form at one end this wedge, beginning at two inches from the end and working it down to a point. A small mallet will be needed—a billet of wood will do.

**Other Matters.**—Grafting wax will be wanted; it may be bought, but it is easily made; melt together in any old iron vessel: Bees-wax, 6 oz., Rosin and Tallow 4 oz. each, over a moderate fire, stir gradually until all is melted. Take from the fire, and as soon as it begins to harden at the edges, stir until no longer liquid. Get some very old cotton stuff made thin by wear and washing; an old sheet, pillow case, or calico dress, whatever will tear in either direction with great ease; tear this into strips one or two inches wide and as long as the material will make; wind the strips upon a stick, as shown in figure 1. As one strip is wound on, put on another, putting its end *under* the end of the strip already wound, as seen in figure 1; remove all threads or ravelings in winding; when enough is wound to make the roll about 2 inches thick, tie it with a bit of thread and make another if needed;

provide a wire at the other end of the stick to hang it by. Melt the grafting wax again, making it pretty hot, put in the rolls one at a time; when thoroughly penetrated by the melted wax, take out, let it drip until the wax no longer runs from it, and hang it where a few drops of wax may be caught by a paper. Treat the other rolls the same. When cool, put away from the dust. Now you are ready

**To Graft.**—When the buds begin to swell, put the above named things; saw, knives, wedge, mallet, a

Fig. 1.

Fig. 2.

Fig. 3.

roll of waxed cloth and the cions into a basket; besides these there will be needed a small box or cup of lard, and rags to wipe the hands upon. It is well to furnish the handle of the basket with a hook to hang it by. A step-ladder is likely to be useful. Having determined upon the place for the graft, saw off the branch, selecting a smooth place free from small branches; with the large knife smooth the cut surface, place the knife across the end and strike it gently with the mallet, to make a cleft as shown in figure 2, leaving the knife in. Now take a cion, and, with the small knife cut it to a smooth wedge, beginning near a bud, as seen in figure 3, the small piece, B, at the side, shows the shape of the wedge, which should be slightly thicker at one side than the other. Now the cion is ready to put in its place. If the branch to be grafted is small, but one cion is put in; the place will heal better if half the branch is cut away, as shown in figure 4. By prying the cleft open with

Fig. 4.

Fig. 5.

Fig. 6.

the point of the knife, the cion is put carefully into the cleft, the lower bud on it coming just at the cleft, as seen in figure 4, A. Here is the nice point; success depends upon having the inner bark of the stock and that of the cion touch as much as possible. Having the graft in place, all the cut portions are to be waxed, as will be described below.

**Two Grafts** are put in if the branch is over an inch through; all goes as before except two cions

are prepared, the wedge placed in the cleft, by which it is held open as the cions are adjusted as in fig. 5. Then to wax the graft, unroll from the waxed cloth a piece long enough, which will soon be learned, tear off a bit to go over the top, between the cions; then a piece to go around this, if the cloth is two inches wide it may be divided into two pieces. All that is wanted is enough to completely cover every wounded and cut part of both stock and cion (fig. 6). The cloth will stick wherever it is applied by pressing it with the fingers; grease the fingers with lard before working with the wax, and wipe them before cutting other cions. A single trial will enable one to wax a graft better than a whole page would tell. A cion with with two good buds besides the lower one is long enough.

**Pruning.**—Large branches may be cut away from fruit trees in mild weather. A saw should be used for this; and the cut smoothed and covered with paint or melted grafting wax. The objects in pruning an old orchard, are to remove unhealthy branches, and to thin the tops of the trees, opening them for the access of sunlight and air. In case trees have grown one-sided, they may often be brought into good shape again by judicious pruning.

**Tree Planting.**—The work of selecting the trees for planting should be done at once, that the nurserymen may have the orders in hand, and fill them promptly. Do not buy of tree peddlers, unless absolutely known to represent a reputable nursery. Most of them are frauds, and their statement of the value of new and high sounding varieties are fiction. A list of some of the best varieties of the various fruits, was given in the January number. Should the trees be frozen when they arrive, place them in a cool place to thaw slowly.

**The Canker-Worm.**—On mild days, the canker-worms may make their appearance, and the females, which are wingless and always crawl, must be prevented from ascending the tree and depositing their eggs. The devices for effecting this are numerous; they generally consist in placing some barrier around the trunk which the insects can not pass. Some have gutters of oil, others smooth surfaces which they can not travel. The simplest, and as effective as any, is stout paper smeared with tar or printer's ink. Blowing dust and dead insects, will bridge them over in time, and to be effective, they must be looked to every few days, and renewed as needed. *The Tent Caterpillar's Eggs* are deposited in rings on the small twigs of apple and other trees, near their ends, and can be readily seen on dull days; they should be cut off, taking the end of the twig, and burned, thus saving a much larger amount of work later in the season.

### The Fruit Garden.

That which has been said of selecting trees, in the "Orchard and Nursery," holds equally good in small fruits of the "Fruit Garden." Select and order at once. Do not rely for a supply upon new and not thoroughly tested varieties. It is well to "take on trial," some of the most promising sorts, and if they succeed, there will be a basis for future increase by propagation. If indulged in judiciously this experimenting with the "new things," is one of the chief pleasures of the fruit garden.

**Pruning** that may have been left undone last fall, can be attended to now. Prune the Grape-vines on the first mild day, and long before the buds swell. The Currant and Gooseberry bushes need to have last year's growth shortened, and the old stems thinned out before they start to grow. Give an application of manure or ashes between the rows.

**Strawberries** may be planted in localities where the frost is out of the ground, as may also be done with

**Blackberries and Raspberries**, both of which start to grow very early, and are better if planted in the fall.

### Kitchen and Market Garden.

The great range of climate our country presents is shown by the fact that while one gardener is looking forward for his work to commence in a month or two, another is tending his growing crops, and is thinking about markets and transportation. Wherever he may be, the successful gardener will

be found in readiness for the busy season when it comes with its rush of work. Frequent inspection of the stored crops in the cellars is necessary as spring approaches to avoid loss from an excess of either heat or cold; the pits must be inspected to see that damage is not being done by mice.

**Roots** still in the ground, as parsnips and salsify, should be dug as the thawing of the soil will permit. Such roots are improved by freezing, being kept fresh and made sweeter, and more tender.

**Cold Frames** need daily attention, especially when the weather is warm, as there is danger of the plants starting too soon and being injured or killed by the return of severe cold. The sashes should be removed altogether on all mild days.

**Vegetable Plants.**—There are so many persons who had rather buy the plants needed for the vegetable garden, than the few who desire to obtain a reputation for always having a good supply can make the growing of them a source of considerable income. To such this is a suggestion in season. The

**Hot-Bed** is the means of obtaining early plants in large quantities. To give all the details of the construction and care is not practicable in a journal. Every one who grows vegetables for sale should have a standard work at hand for frequent reference, such as Henderson's "Gardening for Profit," Brill's "Farm Gardening and Seed Sowing," and Quinn's "Money in the Garden." Hot-beds should be started about six weeks before the time at which plants can be safely placed in the open ground—by the middle of this month for the latitude of New York City. In the *American Agriculturist* for February, 1877, the space devoted to Kitchen Garden Notes was almost entirely given up to the subject of hot-beds, and for fifteen cents, any one not possessing that back number can procure, by sending to the Publishers, a full treatment of the subject.

There is no *Mystery* about a hot-bed, yet farmers, and many others, do without this convenience, from some supposed difficulty in making and caring for it. Sashes, a few boards, and some horse manure, are the materials required. Regular hot-bed sashes are 3 by 6 feet, and may be bought ready glazed at the sash and blind factories; old window sashes will answer as a make-shift, but are far less convenient. Select a place sheltered by a building or fence from cold winds; dig a pit 2½ feet deep, as wide as the sashes are long, and as long as the number of sashes to be used require. Line this pit with rough boards nailed to posts driven down at the corners. The rear board should extend a foot above the surface, and the front one 4 inches above. The front or lower side should face the south. Nail strips from front to rear, for the sashes to slide upon.

**Heating Material.**—Put in the bottom of the pit a layer of 6 inches of leaves, or corn litter; then put on stable-manure, which should have been turned once or twice, to bring it to a state of uniform heat. Put on the manure evenly, and tramp it down; the manure should come to within six inches of the top of the pit; upon this is to be placed six inches of fine, light soil, and the seeds sown in that, or preferably put on two inches or so of common earth on which to set the boxes in which seeds are sown. Put on the sashes, and when the manure begins to heat, test it with a thermometer; when the heat is declining from 100°, seed may be sown in the soil, or the boxes in which they have been already sown should be placed in upon the surface of the hot-bed.

**When the Plants are Up**, give them air every day by lifting the sashes at the rear, not forgetting to shut down the sashes at night; give water as needed.

**Boxes in Windows** is an excellent way of starting plants for early setting, though it must necessarily be on a small scale. For a small garden a good supply may thus be procured. In sowing the seeds avoid putting them in too deep—a half-inch is ample for all, and a less depth is better for the small seeds. Press the soil closely around the seed.

**Varieties to Sow.**—The first plants to go into open ground are: Cabbage, Cauliflower, and Lettuce. For early cabbage, "Jersey Wakefield" is the leading variety, seconded by "Early York," and a second early is "Winningstadt," for general use. Of cauliflower, the "Early Erfurt" is standard; and

the "Tennis Ball" and "Boston Market" are the favorite, leading market sorts of early lettuce.

**Implements.**—The time spent in repairing and painting tools is always well employed, at the same time one can take an inventory of stock and see what is needed for the coming season. A seed-sower should be in use, even in a garden of moderate extent, and now is the time to get that and other implements. In fact, there is much work during this month that comes under the head of

**Getting Ready.**—Bean poles may be wanted, and there is no better time than now to haul them from the woods to a convenient place near where they are to be used, and the brush for peas should be procured before the leaves start. The man who so plans that his season of work extends through the whole year rather than just a few months when the crops are growing, is the wise and successful one.

### Flower Garden and Lawn.

There is not much work outside during the winter months. When heavy snows come—and they often do in February—the evergreens must be looked to, and the snow removed while it is fresh, and before it bends down and breaks the limbs. If the snow is deep it will be necessary to shovel it away from the lower branches of evergreens. If manure has not been spread upon the lawn it can be done now, but it should be well rotted and entirely free from weed seeds. Make all the plans for new paths, drives, flower-beds, etc., and if these are to be of much extent, draw up a plan or map of the grounds as a guide in the work. Cannas and other large roots stored in the cellar will need attention, and all decaying parts removed. The seeds for choice annuals should be selected, and for early growth may be started in window boxes, as noted for vegetable seeds under the Kitchen Garden.

### Greenhouse and Window Plants.

This is the month when the greenhouse and window plants are most appreciated, and the care of previous months is giving its best returns.

**Bulbs** of Hyacinths, Narcissus, etc., may be brought from the cellar and forced into bloom; and a succession of flowers may be continued by still sowing seeds of Mignonette, Sweet Alyssum, Candy-tuft, and other annuals of a like nature.

**Cuttings.**—The boxes, sand, and soil for the propagation of the desired Verbenas, Geraniums, etc., will need to be provided at this time.

**General Care.**—Water as the plants are found to need it. Pay special attention to ventilation, that there may be a plenty of fresh air, and at the same time that the plants are not unduly exposed to sudden changes of out-door temperature. The leaving of the sashes and windows open for an hour, or even less, may so chill the plants as to injure them.

**Insects.**—Use tobacco water for the Green Fly; thorough washing kills the Red Spider. Mealy Bug is best treated by picking off with a pointed stick. Worms in the pots are best removed by turning the ball out when the worms may be found. Syringe all the plants thoroughly at frequent intervals.

**The Jack-Ass Rabbit in California.**—In speaking of the Jack-ass Rabbit in January last, we said that the animal was not found in California, a statement which is perfectly accurate, so far as concerns the animal we were writing about, but not correct according to California customs. As several California friends have pointed out what they consider an error, we will briefly state the facts, which are these; the name Jack-ass Rabbit was originally given to *Lepus Callotis*, an animal with the geographical distribution given in the article referred to. We have the high authority of Prof. Baird, for stating (*Pacific R. R. Reports*, Vol. VII, page 591). "It has not yet been found in California." There is, however, in California, and abundant there, a related species, *Lepus Californicus*, the California Hare, to which it seems the Californians have also given the name of "Jack-ass Rabbit," a name which properly belongs to another animal. We were abundantly aware of the existence of the California Hare, having hunted and eaten it; our mistake was in not knowing that this, as well as the Texan species, was called Jack-ass Rabbit; common names are a source of confusion among animals, as well as among plants.

TO SECURE

## MANY GOOD THINGS

AT

### Trifling or No Cost.

The Month of FEBRUARY has, for many years, been largely used by our readers in gathering and forwarding the names of their friends and neighbors, and, as a rule, quite as many Premium articles are sent out in acknowledgment of such favors, during this month, as during any other month of the year.

This is comparatively a leisure month, and when people are beginning to think and plan for the work of the coming season, they are all the more ready to avail themselves of the helps, the hints and suggestions afforded by the pages of a Journal of this kind.

Our contracts for the Premium Articles and Books, made during the low rates prevailing early last year, enable us to continue the liberal offers, despite the general advance in prices.

It will be quite easy for any one to now obtain the names of two, three, four, and more persons as subscribers, and receive in return the corresponding Premiums or Books offered, at no expense save the cost of delivery, and many of the articles are delivered free.

Every one persuaded to become a reader will in reality be benefited. It is next to impossible for one to go through a volume of this paper without getting some hints and suggestions that will be each worth many times its small cost for a year's subscription. Many will save ten-fold this cost by the warnings given in the Humbug articles.

Again look over the descriptive list of the Premium Articles, and select one or more desirable articles, and then secure them this month.

Premium Clubs of two or more names may consist of old or new subscribers, or both; also of English or German subscriptions.

If the Illustrated Premium Sheet (32 pages) has been mislaid, or not received by any subscriber, a Postal Card request, sent to the Office, will bring another copy at once.

**THERE OUGHT TO BE**, in every neighborhood, at least a few good books on Animals and their Diseases, on General Farming, on Gardening, on Fruits, on Farm Implements, etc., and at least a few Standard Works on other subjects. These books ought to be accessible to all for reference in case of need, as well as for reading by all—a sort of circulating or reference library to be in charge of some one.

Never before was there so good an opportunity as now to get a collection of such Books at very small cost. Any ten or more persons contributing \$1.50 each, will each be supplied with the *American Agriculturist* for 1880, and in addition, one Dollar's worth of Books will be presented for each contributor to the fund. The books may be selected from the list of 847 Good Works named in our premium sheet. Where the subscriptions are mainly sent in for 1880, subscriptions for 1881 may be added, when desired, to increase the Library as far as possible. Many new subscribers can also be found. Every neighborhood may thus secure such a Library. It only needs some enterprising man, young or old, to take hold of the matter as a leader, and he will soon have plenty of helping hands, and heads, and hearts. If the Men neglect it, their "Better-halves," or Daughters, always foremost in good works, should take it up.

containing a great variety of Items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

**Will Present Grain Prices Advance or Decline?** is the burden of many recent letters to the Editors of the *American Agriculturist*, the writers seeming to expect a positive Yes or No by "return mail." We know of no human being able to answer this question. Some hundreds of shrewd business men—those whose life-work is dealing in grain, and who carefully study the whole situation here and in Europe—are now investing their thousands, hundreds of thousands, and in some cases their millions, with reference to the rise or fall in prices during the next two to four months; and these men are about equally ranged on the two sides of this question. Part claim that the deficiency in Europe is so great that there will be a demand for all our surplus, at any price. These are buying and holding all the grain they can, at prices now so high that exports have come to a stand still. The other side claim that Europe will not take all our surplus unless at lower prices than now prevail, and they are contracting to deliver wheat at lower prices than are now current. So the question stands to-day. These great market "doctors disagree," and how shall laymen decide? The Elevators and Storehouses in New York, Chicago, etc., are full of this speculatively held grain. Looking the ground all over, it seems to us that there is about an even chance either way. We can not and will not advise any one to sell or not to sell. As for ourselves, our rule is to sell farm products at the current prices when we are ready to sell and want the money. If prices are likely to go up, there are watchful men ready to pay more to-day; if likely to go down, these same men would sell and not buy. Having sold and got the money, we feel "Well, so much is safe, anyway." If prices go down we say, "Lucky that we sold when we did." If they go up we say, "Well, it was just as likely to have been otherwise," and—no tears are shed.

**Some Pins!**—Less than fifty years ago, and that was in the boyhood of a good many of us and the manhood of not a few, the most rapid production of pins was 14 per minute per man. Now it is over 14 hundred. During 36 years past the Howe Company alone has, according to the *Derby Transcript*, made over fifty-six thousand million (56,246,400,000) pins, weighing 8,000 tons, and stuck them on some 221 million papers. These pins laid down end to end would reach over 33 times around the earth, or 830,909 miles! There are at present ten pin manufactories in this country, able to turn out, in working ten hours a day, over 181 thousand million pins a year, which would give 365 pins to every man, woman and child in a population of fifty millions. That, however, is only one pin a day to each—a small allowance for many families. But with the facilities employed just before the time the *American Agriculturist* issued its first number, to produce the present regular supply of pins would require the constant work of over 7,000 men, and over 17,000 women and children to stick them on papers—the latter work is now all done quickly by automatic machinery.

**The Money Value of Foods.**—To all who are interested in this matter—and the number is very large—we recommend the careful perusal of Professor Atwater's comprehensive paper given elsewhere. *Feeding Stuffs* and *Fodder Rations* are subjects upon which much light is needed by those who have to deal practically with them.

**Lettuce Disease.**—"A. L.," Newark, N. J., brings a quantity of forced lettuce, as a sample of his large crop, with the sad complaint, that it is all rotting away. This lettuce disease is not a new trouble, but one that has done much havoc in market gardens, especially old ones, near large cities. The trouble is caused by a fungus, closely related to the Grape Mildew, and of which we may say more, so soon as the specimens in hand are thoroughly examined with the microscope. With our present lack of a remedy, the growing of lettuce in hotbeds had best be given up for a few years, in these places where it has proved so destructive, as is the case at Newark.

**America and England.**—Perhaps never before has America entered so largely into the very life of England. They may do without our ideas, political and social, but they can not do without our bread. The old land stretches out her hands to the new, and we send her

food that to us, is better than bread cast upon the waters. England has suffered from short crops, while we have had enough and to spare. The results of the year will be seen next spring by a large immigration to our great West, and the now hard-worked and poorly paid British farmer will soon become an independent American.

**The Wrong Street.**—Messrs. Benson, Maule & Co. call attention to the fact that we last month gave their place of business as 223 Chestnut street, whereas their seed store is 223 Church street, Philadelphia.

**An Improvement in Churns.**—No doubt that many who have used the Blanchard Churn have thought it hardly possible to improve it. But the makers thought differently, and presented the "Improved Blanchard" at the Great Dairy Fair in December last. In this churn as formerly made, the top was flat, and the portion of cream thrown against the inside of the cover would escape churning unless care were taken to scrape it down now and then and mingle it with the rest of the cream. The improvement consists in making the top of the churn of the same shape as the bottom, thus bringing all the surface within reach of the dasher, so that no cream can escape being constantly agitated.

## Keeping One Cow.—Prizes.

### The Family Cow—How to Keep Her.

It is perhaps safe to say that there are a greater number of persons who keep but one cow than there are who own ten or more. No doubt many more living outside of closely built cities would gladly lessen the cost of supporting their families and at the same time add to their comforts and even luxuries by keeping a cow, did they know how to keep her. There is a general notion that keeping a cow requires a pasture. If a pasture is not necessary, how get along without one? One has heard that half an acre of land will supply food for a cow. How? Dairymen and farmers can learn how to treat herds as a part of general farm management, or in treatises on the dairy. There are works on cows, but none on the cow. Who knows how little land will keep a cow, and how can the most be produced on that little? It is not a question of large farming, but of high farming; not of dairy farming, but of dairy gardening. To call out the best information required to enable one to keep a single cow with the best possible results, the Publishers of the *American Agriculturist* offer

### Prize Essays on Keeping One Cow.

The Essay need not discuss the selection of the cow or the differences in breeds. Let the writer assume that one has a cow—the best he can get, or his means allow—and takes possession of a place which allows him land for his cow on the first of May. The main points to be considered are: The stabling or housing of the cow; the yard room she requires, and the storage or disposal of her manure. Then the least area of land that can be safely set apart for the support of the cow. How can that land be best managed with reference to that cow? The manner of cropping to obtain the greatest amount of food for the whole year. Shall any crops be sown for next year's use? It is to be assumed that the land is to be made to produce all that it will profitably yield, which will bring up the question of manure and fertilizers, of course considering that produced by the cow herself. What proportion of the produce of the land is to be cured for winter? Roots and keeping them. How much food must be bought, and what? The cow is to be so fed, to be so long milked, and in every respect so treated as to give the best returns of which she is capable to her owner. Time of calving. What to do if help is needed. Treatment after calving; what to do with the calf. Milking. The Essay need not treat of the disposal of or the uses of the milk.—We give these suggestions as to the kind of Essay desired, but the writer is by no means limited to these. The problem is—given a good cow, how to get the best possible returns from the least possible portion of the land through the agency of the cow. The Essays to be legibly written on one side of the paper only, and not to exceed 6,000 words (which is about two pages of the *American Agriculturist* in this type). Sketches for engravings may be sent if desired.

### Cash Prizes.

For the Best Essay.....	\$50 00
For the Second Best Essay.....	25 00
For the Third Best Essay.....	15 00

The Essays to be sent to the Editors of the *American Agriculturist* on or before April 1, 1880, in a sealed envelope with an assumed name, and an accompanying envelope containing the assumed name and the real name and address of the writer. The prizes will be awarded by a committee of competent and impartial Judges. All Essays submitted for these prizes to become the property of the *American Agriculturist*.

**Market Tendencies.**—Those who have watched the markets for the last ten, or even five, years, are impressed with the fact that there is now a much greater discrimination than formerly as to quality. This is true in all departments, fruits, vegetables, etc., but perhaps more marked among meats than elsewhere. Butchers as a class are getting to be very observant and particular, and this is certainly a movement in the right direction.

**Loading Logs.**—"L. M.," Canajoharie, N. Y., sends a sketch and description of a method of loading

LOADING LOGS UPON A SLED.

logs upon a sled, which he has found to be entirely satisfactory. The whole matter is so self evident from the engraving, that an explanation is not called for.

**The Bank of a Creek** in York Co., Pa., is margined by bushes 10 to 15 feet high; the owner, "A. L.," does not like the looks of it and desires to use the land; he wishes to know what he can put in place of the present growth that will prevent the stream from washing the banks, which are in some places nearly perpendicular and in others sloping.... Were the place ours, we should try to modify the present growth rather than to replace it by another, which, as the land is now full of roots would be a most difficult matter. No doubt the thicket can be narrowed, by taking out some of the shrubs upon the land side; then if the remaining shrubs would be more pleasing if more formal, we would convert them into a broad hedge, by cutting them back to a line, making the present shrubs some two feet shorter than the height is to be finally. Now is the best time to cut them, and by an annual clipping a dense and comparatively narrow hedge screen may be very readily formed.

**Killing the Live-Forever.**—There is probably no other weed more tenacious of life than Live-forever. Among the various suggestions for its destruction that we have published, is that of smothering it with refuse hay, to exclude light and air. Mr. J. Northrop, writes from Vermont, that he tried to smother it, and though he put wild hay over it, to the depth of 6 feet, he thought the weed increased under the treatment. One of his neighbors tried to burn it out, using load after load of wood, with no good results. Another neighbor got rid of the plant, by pouring boiling brine upon it. Mr. N. suggests digging up the plants, and putting them in the road, where they will die very quickly. He also says, if the land be rolled with a heavy roller, while the Live-forever is wet, and the field be pastured at the same time, the plant will disappear. The trouble in digging it up is to get all the roots; every fragment left in the soil will grow.

**Ice-cold Water** should not be taken in large quantities by horses just after they have been driven and are warm. Let them rest a while and cool off.

**Do Thoroughbreds Revert?**—In order to obtain facts on this important question, W. H. Brewer, Professor of Agriculture in Yale Scientific School, issues a circular containing the following inquiries:—"1. Have you personally ever known any case where thoroughbred Shorthorn cattle, because of climate, poor feed, neglect, or any other cause, have become in character anything else than Shorthorns—in other words, where, from any cause, thoroughbred Shorthorns have degenerated into animals of any other breed or type?—2. Do you personally know of thoroughbred animals of any other breeds so changing or reverting?—3. Have you ever heard of such a thing taking place, in the experience of other breeders, so well authenticated that you believe it to be a fact?"—If fully responded to, the answers to will furnish material for a valuable report at the hands of Prof. Brewer.

**In-and-in Breeding.**—"A. R. L." This term has been variously defined as far as words go, but the idea is about the same with all, namely: A breeding together of animals that are closely related, such as cousins and those bound by ties of even closer kinship.

**The Bee Moth.**—This insect is very destructive to the honey bee, the larvæ or "worms," working their way through the combs, and in time, if not attended to, becoming so abundant, that the bees are obliged to abandon

the hive. The only effective way to meet this enemy, is to be "first on the ground," and prevent the moths from entering the hives. The insects may be found resting about the hives in early morning, and being sluggish at that time can be easily caught and destroyed.

**Where to Get This and That.**—Many thousands of letters come to the Editors every year (some with and some without "return postage"), asking where they can obtain from trustworthy parties, implements, animals, poultry, seeds, plants, fertilizers, and a great variety of other things, all of which questions we try to answer when we can. But nine out of ten of these letters, and much valuable time of both writers and respondents, would be saved, if the inquirers would take the little trouble required to just look through the advertising columns, where usually, in one number or another, several parties announce the very things asked about. We try to keep out all parties not trustworthy—and do not admit any advertisers whom we would not ourselves patronize when wanting the things they offer. (The Editors have the "veto power" over any and every advertisement proposed for these columns.) It will always pay to read through the business columns to see what is offered and by whom, and useful hints are often derived from reading what others say and how they say it. New ideas are thus started up in one's mind.—When corresponding with any of our advertisers, or sending for catalogues, etc., it is well to state that you are a reader of *this Journal*. They will know what we expect, and what you expect of them as to prompt and fair treatment.

**Heavy Pigs.**—"Dr. C. E. B.," Stonington, Ct., sends an account of some pigs raised by him, crossed Berkshire and Chester Whites, which weighed when dressed 546, 532, and 437 lbs. respectively, being 14 months old; also two spring pigs 8 months old, which weighed 370 and 404 lbs. They were fed on milk and meal, and were sold at 6 cents a pound, which left no profit.

### Sundry Humbugs.

The readers of this column are aware of the frequency with which we have referred to Wall Street speculations. For over a year there has been no one subject upon which we have had so many inquiries as those relating to the circulars sent out by parties in and near Wall Street. These circulars, in some cases a single sheet, and others a handsome pamphlet, showed very plainly that, were their figures true and did everything work as promised, a small investment would soon give a large return; and it was made so clear, that one with a few hundred dollars to start with could soon become a millionaire, that very many sent their money without hesitation to those issuing the tempting circulars; others more cautious wrote to us to inquire.

#### LETTERS CAME BY HUNDREDS,

all of the same purport; with scarcely an exception the writers wished to know the "responsibility" of the parties. So well were the schemes presented that no one seemed to doubt that it was all true, and each seemed to feel that if the parties could be trusted to use his money in "puts and calls," "special privileges," and all the rest, his fortune was sure. Our carefully made inquiries only discovered that the various parties kept large bank accounts and had abundant capital. Indeed, some of these parties brought us strong recommendations as to their responsibility and even respectability, and made us the tempting offer of many hundreds of dollars to insert their advertisements in the *American Agriculturist*. But we could not accept the lucrative offers, and thus become accessory to what seemed to us would be bad for any of our readers thus invited to invest. A singular feature in the matter all along has been that in all this correspondence there came not a single complaint. Though all seemed favorable, we all the while felt that there was a screw loose somewhere. According to the statements, investments of \$5 and \$10 were welcome; the Brokers would make these into \$50 and \$100, and gladly, for a small commission. Now if these brokers had abundant capital, why didn't they invest that, and get the whole profit for themselves, instead of asking for \$5 and \$10 from the farmers in Kansas, Minnesota, and everywhere else to use, when they had a plenty of their own?

#### A LITTLE COMMON SENSE

is a capital thing to apply in such cases. Common sense taught us that these circulars showed that money could be made altogether too easily. Common sense indicated

that were there such easy and safe methods of making money, those who discovered them would not tell all the world and advertise for strangers to come in, but keep the secret for themselves and intimate friends. This view of the matter, and the general "ear-marks" that one can hardly describe, but which, whoever has had long to do with such schemes, "feels in his bones" rather than sees with his eyes, made us quite confident that there was something rotten about it. We had had not a single complaint, and their bank account was large, so we had no grounds upon which to base an exposure of the parties themselves. (It took months of careful, earnest investigation and trap-setting by sharp detectives to finally unearth their swindling.) But we could help our readers, and warn them against the persuasive circulars by an exposure of the business without reference to the parties engaged in it. Nearly every month, for a long time, we have endeavored to show how stock speculations of the kind proposed were regarded in business circles, and that the sound, reputable merchants, bankers, brokers, etc., all looked upon the "put and call" business as *the meanest form of gambling*. But the end has come, our suspicions, or prementiment of wrong doing, are more than fulfilled. All of these remarkable "Brokers," who occupied such stately offices, and sent out pictures of them, who had such special advantages, and who could invest the money for others so profitably, turn out to be

#### THE MEANEST KIND OF SWINDLERS,

and must take their place with those who "shove the queer;" those who sell \$15 Bibles for a dollar; the man who is in search of his cousin—in fact, they step to their places in the ranks of the great army of cheats, frauds, and swindlers, who prey upon the honest and unsuspecting, dealing in bogus stuff of all kinds, from flash jewelry to bogus lottery tickets to which there is no lottery and every ticket bound to draw a prize. In fact, it is alleged that the great Pattee, who a few years ago was the head and front of the Wyoming and various kindred lottery schemes, was actually the capitalist of

#### TWO OF THESE BROKERS' SHOPS.

Four of the leading establishments in this "stock" business are said to have been practically under the management of one man, Buckwalter by name. These were Lawrence & Co., Adams, Brown & Co., Allen, Jordan & Co., and Barnes, Garrison & Co., Buckwalter owning the first two entirely, and half of the others. Much trouble was caused by these scams taking

#### THE NAMES OF REPUTABLE BROKERS.

Thus the house of Lawrence Bros. & Co. stands high, and the name of Lawrence & Co. was sufficiently like it to be very annoying; so one of the largest houses in the city is A. Belmont & Co.; the name of another of the concerns, Thatcher, Belmont & Co., conveyed to those abroad the idea that they were the Belmont & Co. The annoyance caused by these establishments, and their operations bringing discredit upon those engaged in legitimate stock brokerage, induced the Law Committee of the Stock Exchange to employ a law firm to collect information as to these operators and to endeavor to put a stop to them. At the proper point the services of Mr. Anthony Comstock, Special Agent of the Post-Office Department, were called in, and as a result the disreputable firms were hit in their most vital point—

#### THEIR LETTERS WERE STOPPED!

The case being reported at Washington an order came from the Postmaster General to the Postmaster at New York forbidding the delivery of all letters directed to the firms named above, and to half a dozen more all in the same game. Of course stopping their letters ended their business, for these chaps operated entirely through the mails. Next to the stoppage of the delivery of their letters the most important step is the seizure of the lists of names of persons all over the country; books containing thousands and thousands of names were seized, and these are the most important of all the assets of these concerns—the chief stock in trade. It is gratifying to know that this wicked business has come to an end, at least for the present. Perhaps those who made remittances to these firms would like to know

#### HOW THEIR MONEY WAS USED,

whether on "special privilege" or "put and call." They used the money very judiciously—one of the chaps "put" it in his pocket and it wasn't possible to "call" it out again. Stocks? they had nothing to do with them. They knew a trick worth two of that; besides, stock speculations are risky and some think immoral. It was a very neat business—all profit. Mr. Buckwalter's monthly income from the four concerns named above was to be over \$22,000.—It must be a highly consoling reflection to those who have contributed their \$10 or \$20 to make up this amount, to read that he "is said to be handsome in appearance and singularly winning in manner."—"Winning!"—we should say so. How he *did* win!

When these schemes for making money so readily, are presented, no matter how persuasively to those living at a distance, when the figures show with convincing cer-

tainty that an investment will pay 20 to 50 per cent, it is well for those who feel tempted to remember that

NEW YORK CAPITALISTS ARE NOT ASLEEP.

They have millions awaiting investment in anything that will be reasonably safe and give a fair return. Any thing so sure as these stock schemes were represented to be, if it would pay 10 per cent, would be jumped at. It is very certain that no really safe, profitable business would be hawked all over the country seeking investment in small drihlets. Every good and safe chance, every chance to invest money that we could commend to our friends, is wanted in New York. The very fact of its going abroad is evidence that it is not of a kind wanted here. We have given considerable space to this

BOGUS STOCK SCHEME,

as it is the most important, so far as the amounts concerned go, of anything yet attempted, and the most pernicious. It could never have been checked but for the law that prevents the use of the mails for fraudulent purposes. There will be an attempt, possibly at the present Congress, to either repeal the law, or so amend it as to destroy its efficacy. The law stands in the way of those who have a vast money interest in its repeal. It is to the direct interest of no one to lobby in its favor. The *American Agriculturist* goes into politics so far as to advise its readers to let the law-makers know that this is a most beneficent law, and one that must stand. ....Now that the planting season is near at hand

THE VENDER OF WONDERFUL PLANTS

will be around. He has already been in Norfolk, Va., with the Blue Moss Rose, for which he only asks \$5. If he will bring a real Blue Rose, mossy or not, he can readily get \$500, if not more. There is the firm our correspondent asks about in Geneva, but they never authorized such a fraud as this pretended agent is. Do not hny any unusual things: Strawberries that grow on bushes, Self-pruning Grape-vines, the Peach budded on the French Willow, or any other of the marvels of horticulture... Among the old things that have revived of late is

THE SELLING OF RECIPES.

If persons who bought these recipes merely lost the money paid for them, it would not much matter, but the evil does not end here. One of the most common recipes is that for some kind of illuminating oil; sometimes it is "Solar," or "Centennial," or "French," or other high sounding name, but all are equally dangerous, as, so far as we have seen them, they have for their basis

THAT MOST DANGEROUS LIQUID, BENZINE.

There are several things added, but they do not in any manner change its character, nor is it possible to change it by the addition of anything. In view of the fact that these recipes are now sold, we must repeat our warning against them. If any one has paid a dollar or any other sum for a recipe making an illuminating oil with Benzine, do not be tempted to use it. Benzine is very volatile, and its vapor mixed with air will explode. Those who sell the recipes claim that the oil will not explode.—Of course not, *Oil* never does explode, but the vapor when mixed with air will—dangerously—fatally. It is very amusing to read the high sounding threats on these recipes, that the holder is "not to divulge or make known any of the ingredients."—"Under Penalty of the Law." Bosh!...The "Dictionary" scheme is quiet, but

"THE NEW DOMESTIC BIBLE"

offer, noticed last month appears to have had quite a run, as some papers of generally good reputation have published the advertisement. It is strange that one can read the advertisement and not see the catch. It gives a cut of a fine large Bible, and it also describes one worth \$15, and then states: "In order to introduce our Bibles, we agree, upon the receipt of 75 cents, to pay the postage and other expenses, to send any reader of this paper a copy of the Holy Bible."—Mind, he don't agree to send *that* Bible. "A copy of the Holy Bible" is pretty good for Philadelphia; she will soon equal New York, or even Cincinnati, in the Hamburg business if she keeps on.... A School of Design is a good thing in any city, but

"A NATIONAL SCHOOL OF DESIGN"

is the kind they have in Chicago. They advertise to send an "original oil painting," worth \$10 or \$15, for 25 cents. One of our friends seeing the advertisement thought to please his picture-loving wife. He received the painting, and sends us half of it, the other half went to the paper in which he saw the advertisement. "Original!" we haven't the least doubt of it. We don't think that any one—not even those who decorate the panels of street cars and omnibuses, could be any more original—it is the *originalst* painting we ever saw. This "School of Design" designs lots for 25 cts. in the sign painter style. Our friend should not complain; we don't think he could get such a picture anywhere else for half the money... It is so long since we have had a good, "hang np," real A No. 1 cure-all, that it is rather refreshing to get hold of

SOMETHING NEW IN THE MEDICAL LINE.

Here it is, a rather neat pamphlet, all bright and fresh

from the press. It is headed: "Truth is Mighty, and Will Prevail."—If our memory serves us, we have heard something like this before. Then here is a picture; an old man on a bed, a young man, a bureau.—The room looks familiar. We must have seen that before. Then the story—these medicines always have a story. It is at one time a visit to "Old Mother Nohle" (what has become of her and *his* diamonds?). Again it is Eddie Eastman among the Indians, and Eddie's wife too among some more Indians.—Eddie, "we have missed you."—All these stories come before us with touching freshness. But this story: Bedside of aged father—eve of departure to "that bourne"—universal remedy—about to be revealed—all except myself to retire—old-fashioned bureau—instructed me to touch secret spring—recipes for the manufacture and preparation of his valuable remedy."—Pshaw!—its just that same old, old story that's done service over and over again, and is again revived, and now does service for "THE SYSTEM RENOVATOR, & BLOOD PURIFYING SYRUP."

Of course it cures everything. You have only to "purify the blood," and "renovate the system," and there you are. "Liver complaint?" read the symptoms—every one has them—"Consumption?"—read the symptoms—so many, you must have some—Remedy—Take the aforesaid—and so on through the whole catalogue. It is melancholy to think that people will read this stuff and believe it—and what is worse, take the medicine.

**Starting a Fire** is a familiar daily exercise for thousands of thousands throughout the United States at this time; but there are many who do not know the best way. *Concentration* is the leading feature in this little, but very important domestic duty. 1st, the fuel should be *concentrated*, that is, put together in a compact heap; and 2d, in a place on the grating where the draft can be *concentrated* upon it. These two points gained it is an easy matter to produce a brisk fire. When the kindling, which we have presupposed was dry and in sufficient quantity, is well started, the wood or coal, as the case may be, is so put on that the draft and flame will pass directly through the fuel. In starting a fire, all depends upon having the conditions right, and great loss of time, and even patience, is incurred if they are not provided.

**To Dress Skins With or Without the Fur On.**—"C. L. B." Saratoga Co., N. Y. Tanning is done by means of hark or other substances, which contain tannic acid; this combines chemically with the gelatine of the skin, and forms what we know as leather. But the dressing of skins with some astringent salts—as Alum, for instance—is called *tawing*, and not tanning, as no tannic acid is used. The hair is removed from skins by some alkaline matter, as lime or wood ashes, and with small skins this may be used as a paste spread upon the flesh side and left for a few days, when the hair may be rubbed off with ease. The alkali destroys the "roots" of the hair (the bulbs in the hair follicles), and so loosens it from the skin. The skins may be *tawed* by spreading a mixture of equal parts of finely powdered Alum and Salt upon the moist flesh side, doubling each one, or laying pairs with the flesh sides together and putting them away for several days. After the skin has taken the character of leather, it is to be stretched, scraped, rubbed with chalk and pumice stone until smooth and pulled and stretched while drying to make it soft.

**Eggs from Different Breeds of Hens.**—A western egg-raiser, from his own and others' experience, formulates the following table of weight and number of eggs produced by different breeds of fowls:

Kind of Breed.	No. of Eggs per pound.	No. of Eggs per year.
Leghorn.....	9	160
Hamhurs.....	9	150
Light Brahmas & Black Spanish	8	130
Polish.....	9	125
Black and White Cochins.....	8	125
Dark Brahmas.....	8	120
Plymouth Rocks.....	8	115
Bantams.....	16	90

**Cross Breeding of Sheep.**—"B. Bro." Merinos are greatly improved as mutton sheep by crossing with Cotswolds or Leicesters; the former cross makes a large heavy-bodied sheep, with a valuable, medium, long combing wool; the latter cross is not so favorable, but is a good mutton sheep. The information given on cross breeds in "The Shepherd's Manual" contains all that has as yet been learned or done in this way. Cross breeding must be done from year to year, and it is not a permanent operation, for after two or three crosses the produce is not to be distinguished from the pure breed used for the male animal.

**Census Assignments.**—Prof. C. S. Sargent, of Harvard University, has charge of the department of Forestry, and Prof. W. H. Brewer, of Yale College, is employed as expert on Cereals. The Cotton is placed in charge of Prof. Hilgard, of the University of California, and

special work in the agricultural department, has been assigned to Hon. J. R. Dodge. Such names as these, are an assurance of thoroughness in this important work.

**A Wooden Mailing Money Box.**—Since fractional currency has gone out of use, remittances by

Fig. 1.—THE PINE BLOCK BORED.

mail, of sums less than a dollar, must be made in coin. The sending of coin by letter is both inconvenient and unsafe. A heavy coin is easily detected, and can be abstracted by a dishonest person, or it may wear its way through the envelope of its own weight. A correspondent recently having occasion to send us some silver "change," inclosed it in a wooden box, which he made as follows: A pine block, a trifle larger than shown in figure 1, was bored nearly through in the center, with 1¼-inch auger bit, the "worm" passing entirely through, and thus furnishing a small opening to allow the postmaster to inspect the contents. A cover of thin pine, fastened by four tacks completes the box, as shown in the engravings. The whole can be made in five minutes. When filled, wrapping paper suitable for the directions is *tied* around it with a string. The post-office regulations require 2nd and 3d class matter to be tied. A box of cigars *nailed* is subject to letter postage, and so of other boxes nailed together, if the contents are not visible. We have illustrated the box as it shows ready resources in an

Fig. 2.—THE BOX READY FOR MAILING.

emergency. Our correspondent did not postpone or give up sending the amount of his subscription, because he had only coin. Coin would not be safe in a letter, he had no suitable box, so he at once made one. We have received insects sent by mail, put up in wooden boxes in a similar manner, though in these cases the bore was smaller, and made in the direction of the grain of the wood.

**Sowing Clover Seed.**—Just after a light snow is a favorite time with many in which to sow clover seed—as the seed can be distributed very evenly, and it falls into a good moist place as the snow melts. If Red Clover is sowed alone, about 20 pounds per acre should be used.

**The Agricultural College of Japan.**—This Institution has been in existence for three years, and a large number of students have been educated in it. The government appreciates its work and its needs by engaging foreign teachers and aiding it in other ways.

**Sharpening the Horse-Shoes.**—At this season which abounds in ice, the horses' shoes demand attention that they do not become smooth and thereby subject the animals to cruel strains that may develop into wind-galls, ring-bones, etc. The horse's instinct teaches him he is unsafe with smooth shod feet when driven upon icy roads, and he is constantly in fear, and trembling, lest he slip and fall. It is costly and cruel to drive horses thus shod. The calks should be of hard steel and kept of even length that the weight of the body may be distributed evenly over the muscles of the limbs. If one has not "Self-Sharpening Shoes" it will pay to make frequent calls at the blacksmith's shop so long as the ice lasts. Give the horses a safe footing.

**Butting Rams.**—The butting of an ugly ram, and especially of one just starting out in the business, is not to be winked at. Too many valuable and otherwise harmless animals have been made intolerably ugly by boys, and sometimes older persons, teasing them in butting while they were young. To cure a ram that is continually on the defensive is not an easy task. The following has been suggested as a remedy, founded upon the fact that when a ram butts, he steps back a few feet to prepare for his work. Two long poles are attached to

REMEDY FOR BUTTING RAM.

the horns, one on each side, to drag on the ground, as shown in the engraving, the hacking up of the ram will be so interfered with by the poles, and it will upset him so much that his butting intentions will be modified or diverted. In a short time one stick will be sufficient, and after a while the cure will be effected. This treatment will be employed only when the ram is specially valuable; else he had better be fattened and pass into mutton.

**Apple Trees in Kansas.**—R. Stauffer, Nemaha Co., writes that the warm weather last autumn caused the young apple trees to bloom and push their leaves; also that some trees have the bark killed upon one side of the trunks. It would be for the future good of the trees that have bloomed to cut back the shoots to strong buds that have not started. The injury to the bark is due, as he suggests, to the sun in winter, and may be prevented by shading the trunks; this may be done by loosely winding a hay or straw band around them, or by binding a few corn-stalks upon the sunny side. Another method is to tack two light boards together like an eaves trough, and secure this against the trunk during winter and spring.

**The Ohio State Horticultural** is one of the societies that always have interesting annual meetings and the accounts of the one held at Canton, Stark Co., in December last, show that in spite of rain and mud, there was this year the usual good time. The election resulted in the reappointment of the former corps of very excellent officers, among whom are Doct. John A. Warder, North Bend, of Pres't.; Geo. W. Campbell, Delaware, Treasurer; and M. B. Batcham, Painesville, Secretary.

**Lanterns in the Barn.**—Canton is always necessary when kerosene is burned, but never more so than when used in the barns and stables. A candle well secured within a frame of glass for use in the barn, is cheap, handy, and, above all, comparatively safe, even if it should fall from its support. Do not use any lantern in the barns and stables if it can be possibly avoided.

**Mending Harness.**—When a harness breaks it is always just at that time and place when the break is of the greatest inconvenience. There are two ways of meeting this matter. 1st, by keeping the harness in good repairs, that no weak spot may exist when the trying time comes; and second, to be prepared for a break, should it come, by carrying a coil of strong copper wire either in the pocket or in some place in the vehicle, and a knife for doing the necessary cutting and punching of holes. A good teamster should be an expert in meeting all "break downs," by being able to overcome them.

**Doing Chores.**—Much time is lost by farmers in doing the chores. This loss may arise from several causes; often in the arrangement of the farm buildings, and that of the stock; "things" are not handy. The hay that is fed to the sheep is sometimes on the other side of the barn, and must be carried a long distance by the forkful. This is but an illustration of what may be the case with the corn, litter, and especially the water. Even if the arrangements are perfect, there must be a method in doing the chores: a time as well as place

**"Pine Straw,"** which is not properly straw, but the dry, fine, needle-shaped leaves of the pine trees, makes only a fair absorbent for liquid manure, as it is so resinous and woody. For the same reason these leaves are not easily decomposed and can not rank high as an element in a compost. When any other kind of leaves,

straw, leaf mould, or muck, can be obtained, but little time should be spent in gathering pine straw. If they are at hand in abundance, it will pay to use them. Their best use is as fuel, though they burn too rapidly. A few years ago some one proposed, by means of a powerful press, to make them into blocks to be used as fuel. Whether this was tested or not we have not learned.

**Food and Digestion.**—The value of a food does not depend entirely upon the amount of nourishing ingredients it contains, and a chemical analysis, while it may, does not of necessity show the exact feeding value of fodder, roots, etc. It may be that in the influence that the food has over the digestion its greatest value lies—stimulating it to healthy and vigorous action, etc. Thus turnips are a poor feed in themselves, worth only \$2.80 per ton as far as the food elements go; but they are worth much more, as a matter of practical experience, in the relish they give the stock for dryer and more substantial food. Another reason may be found in the fact that in much food—especially the different kinds of fodder—the nutritive portions are in the cell of the plant—shut up as it were in little wooden cases. The chemist who takes all needed time for an analysis, can work at the fodder until he gets out all the nutritive matters there are in it, and use various methods of doing it. On the other hand, in the laboratory of the animal's stomach the fodder can remain but a limited time, and only the same process is used for all kinds of food, hence the animal may not be, and generally is not, able to remove all the valuable ingredients that the chemist has shown it to contain.

**Curry the Cows.**—No animal of the farm will show signs of neglect so soon as a cow. The coat gets rough and dirty, and the bones stand out with irregular and peculiar prominence. On the other hand, as a matter of course, good care gives the opposite appearance, and the creature is neat, clean, and plump. There is much in a good supply of wholesome food, but it, without occasional rubbing and currying, will not make the cow look and feel comfortable. It pays to curry the cows.

(Basket Items continued on page 75.)

### Bee Notes for February.

BY L. C. ROOT, MOHAWK, N. Y.

During this month bees require but little care; while they should be left as nearly quiet as possible, the bee-keeper in the meantime may be actively engaged. In travelling through the country, I observe that not one bee-keeper in ten has taken enough interest in the business to advance beyond the use of the old-fashioned box-hive. This fact is almost beyond comprehension, when we compare this manner of keeping bees with the better methods of the present day. It would be difficult to innumerate in a single article the merits of a movable comb-hive with each comb huilt in a separate frame, as compared with the old box-hive with crooked immovable combs, the condition of which can be but very imperfectly ascertained. With such movable frames, the bee-keeper may avail himself of the advantage to be gained by using artificial comb-foundation, thereby securing straight worker combs. When desired, such combs may be lifted from the hive and their exact conditions ascertained. The bees may also be brushed from them, and by the use of the Honey Extractor the honey may be removed and the combs returned to the hive to be refilled. The power we obtain by the use of these frames to control swarming, is enough to command the attention of every bee-keeper. Many have said to me that if it were not for the trouble bees would give them during the swarming season, they would keep a few swarms. A minister of my acquaintance disposed of his bees from the fact, as he said, that they were sure to swarm on Sunday. All such annoyances may be avoided if the movable comb-hive is used understandingly. Do not make the mistake which so many have made, in thinking that simply securing a movable comb-hive, and placing a swarm of bees in it, will result in any marked advance over the old way. We should understand these advantages before attempting to profit by them. The facility with which the timid are enabled to perform the necessary operations in advanced bee-culture is likewise a great improvement upon the practices of earlier days. Close-fitting rubber gloves, a modern bee veil and the Bellows

Bee Smoker, will enable the most timid to handle bees with perfect safety. The particular object of these remarks is to induce the beginner in bee-keeping to spend these winter months, when not crowded by the busy season's operations, in investigating these improved methods of our pursuit. After deciding upon the course to be followed, all needful preparations should be made before the busy season opens, in order that no time need be lost when the harvest once fairly begins.

### Cutting Fodder and Litter.

With a fodder-cutter of the right kind, it may even pay well to cut the litter used for bedding

Fig. 1.—PLAN OF ARRANGEMENT.

cattle. This has been tried by the writer with advantage by means of a simple arrangement. A machine which will cut straw or coarse hay in longer lengths than is usual for fodder, is preferable to any other; cutters are now made that can be changed so as to alter the cut from half an inch to an inch and a half by the mere moving of a cam. This may be used for cutting feed or litter. A "Common-Sense Fodder-Cutter" was procured and fixed in the middle of the second floor in the cow-barn. A trap-door on each side in the floor made it easy to drop the cut straw on one side to the standing stage below, where the cows were tied up; and also to drop the cut hay or fodder into the feed-box on the feeding floor, without moving the machine. A plan of the arrangement is shown at figure 1. With the cutter referred to, a whole sheaf of straw may be cut at once into chaff 1½ in. long for litter, and if straw is used for feed, the cut could be changed to ½ or 1 inch instantly, the

Fig. 2.—THE COMMON-SENSE FEED-CUTTER.

knife passing through 4 inches of straw or hay with the greatest ease. Either hand or power may be used, and a wind-mill attached to the end of the barn would furnish a very cheap and effective power for the purpose. One peculiarity of the cutter mentioned, in addition to its automatic and instantaneous change of cut, is that it has a direct cutting action, and a draw motion is given to the knife by its peculiar scythe-blade shape. At figure 2 we give an engraving of this particular machine. There are many other good fodder-cutters, some of which have been described and illustrated in these columns from time to time. Considering the large number, and the excellence and profitability of these machines, it is very clear that farmers should avail themselves of their use, to cut fodder, and in many cases to cut even their litter.

## Fencing and Fences.

### What We are Aiming At.

Many letters of inquiry will be answered, by simply stating the object and aim of these chapters on fencing: As previously noted, the cost of fencing is enormous. Half the fencing in the country is needless and *should* be abolished, and will be when the best system of farming is adopted, and proper laws in regard to animals as "free commoners" are enacted and enforced. That time has not arrived. "Soiling" cattle will come gradually into practice in the older settled States, but a large amount of fencing will be necessary wherever domestic animals are kept at all. Almost half of our country is devoid of wooden fencing materials, and in most of the rest, timber is disappearing and increasing in cost. Wood fences,—except those of chestnut, locust, red cedar, and a limited number of other woods, none of them abundant—decay rapidly, and need constant repairing and renewing.

Now we have every reason to believe that Iron and Steel can be utilized in the construction of fences that will be better, cheaper, and ten times more lasting than ordinary wooden structures. The supply of iron (and steel made from iron) is inexhaustible, and cheaper modes of production are rapidly developing. The aim of these chapters is to not only gather and disseminate what is already known as to iron and steel fencing, but also to stimulate invention in that line. A large number of letters from men of inventive minds, with sundry suggestions and questions, show that a good effect has already been produced. The wide-spread interest in this subject is manifest in the fact that tens of thousands of extra copies of our past two numbers have been called for.

### Metal Fences vs. Prairie Fires.

There is one important point, not previously referred to, in favor of metal fences, posts included, for the new prairie pasture lands, where the annual burning of the grass takes place. Such fences will not be consumed, though if not standing on a strip of plowed land, they may be warped and slightly injured. As is well known, a great amount of fencing is annually destroyed by these prairie fires. This consideration alone is a strong point in their favor. As plain wire is practically useless, the barbed wire, with all its objectionable features, will be used, until a better metal fence is supplied.

### Relative Cost of Iron and Wood Fence.

Many letters ask us to give the present difference in the cost of wood and iron or steel fences. We have not yet gathered all the data which we shall be able to give, but some approximate figures may be presented. For a comparison take the common post-and-board fence, and the Improved Brinkerhoff Steel Strap (No. 19), or any of the forms of Barbed Wire given last month on page 11. The price of these in quantity may be estimated at 11 cents per pound, 1 pound to the rod. The cost of boards 16½ feet long and 6 inches wide we will put at 12 cents each, that is, \$15 per 1,000 feet board measure, which is below the actual cost at points distant from the lumber regions. Suppose also that it is practicable to set the posts 8½ feet apart from their centers. The steel strap or wire fences require only one post to the rod. The cost of the posts we will reckon at only 12½ cents each, which is below the average. We then have

FOR 100 RODS OF FENCE.

Post and Board.—4 Boards, Galvanized Steel Fence.—  
High. 4 Strands High.

400 boards at 12c.....	\$48.00	400 rods at 11c.....	\$44.00
200 posts at 12½c.....	25.00	100 posts at 12½c.....	12.50
50 lbs. nails at 4c.....	2.00	100 staples.....	.75
Labor about (?).....	25.00	Labor about (?).....	10.00
Total.....	\$100.00	Total.....	\$67.25

The cost of labor will depend upon whether the posts are driven, or set in holes dug by spade, or by post augers. The cost will be only half as much for the Steel Fence, as only half as many posts are used. The cost of erecting the board fence will be several times greater than putting up the metal straps or wire. It is a very safe calculation to say that post and board fence will cost nearly 50 per cent more than the metal fence; that if 100 rods of the post and boards can be put up for \$100, the

metal fence will not cost over \$70. No allowance is made for saturating the boards with any material to give them a fair durability. Once put up, the metal fence will outlast half a dozen wooden fences, except the posts, which will have the same durability in either case.

### Is There Any Doubt Then

that metal fences are to be preferred on account of cost, durability, and frequent repairs? The comparative effectiveness of the two is the chief question to be decided; and if this be settled in favor of the metal fences, the only question will be, which is the best kind of metal fence.

### Iron Fence Posts.

A serviceable, effective, cheap, easily erected Iron Post, for general use in ordinary farm and prairie fencing, is now of great importance, and we give here a few more of the forms presented, not so much for their practical value in all cases, but as suggestive in calling out or producing new devices and

Fig. 14.

Fig. 15.

inventions. Some other forms have been contributed, but they have not yet been perfected, or proper sketches of them have not yet been prepared.

Fig. 14 represents one of several contrivances devised by the writer for supporting small or large iron bars used as fence posts. In this form three flanges, or wings, are cast in one solid piece, with a hole in the center of the top, through which the iron rod is inserted. The wings are thin iron plates running out to sharp edges at the wide bottom ends, so that they can be readily driven into the ground, and the post bar driven through, as shown in section in Fig. 15. There may be three or four of these wings; if set in the right direction probably three would suffice to resist the post's swaying to either side, and also resist the ordinary strain in the direction of the length of the fence. The hole may be of any form and size desired, for a round bar of any size, or a flat bar, or it may be large enough to receive a small wooden post. So also the wings may be of any size, length width or thickness required by the character of the soil, the distance apart of the posts and the consequent strain upon each. They may be curved or triangular, or of any form desired. The hole may be a short tube with the wings extending out from its sides. The center part around the hole may be of any thickness and strength required. For ordinary posts in firm soil, the wings one-eighth inch thick, 8 to 12 inches long, and 4 to 6 inches wide at the bottom ends would probably suffice, or even less than these dimensions, reducing the weight to 4 or 5 lbs. and the cost to 12 or 15 cents, or less even; while for soft, yielding soil, and for an extra strong fence, the dimensions may be much increased, without corresponding increase in weight. As the upper edges of the wings curve downward after leaving the post, they are mainly out of the way of cultivating close up to the fence.

A wooden fence post for soft, wet ground has been devised for his own use by Mr. John Bartlett,

Fig. 16.

Fig. 17.

of Oshawa, Ont., as shown in figure 16. It is constructed of durable cedar; the base 3 to 4 feet long and of 4x4-inch stuff, or of any desired size and

strength, is set as far into the soil as may be necessary, and the upright post is dovetailed into it, as illustrated. He saturates the bed-piece, and especially the joint, with a hot mixture of gas tar and pitch, both to preserve the timber and to set the joint more firmly.—Mr. Bartlett sends the sketch, figure 17, for using an iron bar as a post on ground too soft for supporting it alone. The upright, A, is ½ or 1 inch round iron, bent as shown, the end E, entering an auger hole, and a strong staple, D, is driven over the angle. The bed-piece, B, is 3 to 4 feet long, of any width and thickness required by the soil, saturated with pitch as above, and set at any desired depth in the soil.—Mr. Bartlett also sends us (fig. 18) another device of his own for soft or other soils, which, though differing in form, is similar in principle to several other posts. This is a cast iron collar, of the form shown, of any size, and set at any depth required by the texture of the soil. If necessary, iron rod braces may be added on two or on the four sides.

Fig. 18.

James C. Carpenter has devised a form of Fence Post, shown in figures 20 and 21. The ground piece of cast iron, shown by figure 20, is 11 inches long and 5 inches across the top, with flanges on each edge, and two loops for inserting an iron rod. This is driven into the ground, as shown in figure 21, and the iron post rod driven through it. The upright is a bar of round iron, ½ to 1 inch in diameter. Notches filed in or struck in with a "cold chisel" are made at the desired heights for the horizontal wires, and the latter are bound against the notches

Fig. 19.

Fig. 20.

Fig. 21.

with short hits of wire, the ends twisted together with heavy pinchers. (The middle wire is left unbound to show the notch.) Weight of foot piece (fig. 20), 4½ lbs.; of ½-inch diameter round bar, 1½ lb. per foot, say 9½ lbs. for 2 feet in the ground and 4½ feet above ground. Figure 19, a device for driving the iron post rods, is a hollow tube (a large gas pipe) to slide loosely over the post, with a hammer weight upon the top.

### About Barbed Fences.

When beginning this discussion anew, three months ago, we confess to having been almost ready to condemn nearly all, if not all the barbed fences in general use, from the fact that we knew of many instances of severe injury to valuable animals, and from the strong opinions against their use expressed to us by intelligent men of good judgment, some of them having had opportunity for extended observation. Our objections have been somewhat modified by recent letters from our readers. Some write in effect, "our animals were more or less injured at first, and almost every steer gives them one trial, but hardly ever a second one; they remember the pain, and they keep at a safe distance thereafter."

An Important Suggestion comes to us from a subscriber in Western Kansas (his address we have mislaid for the moment), who has had considerable experience with barbed fences—a suggestion that may count somewhat towards obviating the strongest objection to barbed fences. He raises a line of low embankment along under the fence wires by turning in furrows from either side. The ridge thus formed, together with the furrow left on each side of it, arrest the attention and progress of animals before they actually reach the barbed wires, and helps prevent their being injured seriously.

[EXPLANATORY NOTE.—The "Horse-nail Barb" (No. 1) was described in our last two articles, as practically the first attempt at barb-fencing. This has been called in question very strongly by correspondents, and it appears to be a point of some interest in the litigation among several owners of barbed-fence patents. We desire, therefore, to say that we know nothing as to the history of the matter, and care nothing. We gave the "horse-nail" story as we heard it, as it seemed very plausible, and on this account we supposed it true. Our sketch was made from a specimen now in our office, which we found in our search after samples.—The history of barbed-fencing may be of decided importance to patentees, and we have seen scores of pages on the subject, in print and in manuscript. What we are after in these talks is to get at the best present forms of iron or steel fence, taking into account effectiveness, safety, economy, and durability, with a little care also for good looks; and not only to gather and present to our readers all the information we can, but also to stimulate further improvements in this direction.]

No. 27. "Flexible Wooden Barbed Fence."—This is made of wooden strips, about an inch square and 4 feet long, with hooked attachments on each

end, and pieces of wire put through at any desired distances apart to serve as barbs. After completion, the wooden strips are soaked in hot coal-tar or hot paint of any desired color, and transported in bundles. Among other points, it is claimed that it is flexible, is seen by the animals, and is little affected by heat and cold. We have not seen it in use, and can not judge as to its strength, and do not know its cost. Properly saturated it would be durable, but not be proof against prairie fires.

No. 28. "Betts' Ready-Made Wire Fencing."—This consists of six No. 10 wires firmly stapled to upright pickets, 15 to 30 in a rod. The pickets are, say 1x1½ inch and from 2½ to 5 feet long, as desired. They may be of uniform length, or alternate long

and short ones. A very ingenious machine rapidly applies the pickets to the continuous wires, distributes and drives home the staples, and winds the whole in a roll, the rolls usually containing about 6 rods each for transportation. It is fastened to the posts with staples over the wires. Among the claims for it are: that cattle can not get their heads

between the wires; that the wires mutually support each other and fewer posts are needed; that animals can see it and will not run against it; that it is portable, and can be moved by drawing the staples and rolling it together; that it is ornamental, etc., etc. The cost varies from 90 cents per rod for undressed pickets, 15 to rod (weight 20 lbs. per rod), to \$1.60 per rod for 30 long and short, dressed and pointed pickets to the rod, having a weight of 32 lbs. per rod. Albert C. Betts, Patentee.

At least half a dozen of our readers have sent us samples of various forms of wooden, and especially of tin "tags," to be attached to both plain and barbed fence wire as signals which may be seen by

No. 29.

animals that would otherwise run against and break the plain wires, or be injuriously wounded by barbs. We select the first sample at hand (the sender's name is not given with it). The tags are bits of bright tin of any form, cut from waste scraps and hung on one or two feet apart, more or less.

No. 30.—Mr. John Bartlett, of Ontario, referring to the barbed-steel strap, No. 21, sends us No. 30, which he suggests would save the waste of cutting out, and perhaps be effective. Two cuttings are made in the side of the strap, leaving a cone-section barb in the center, and the two corners are turned out as horizontal barbs, one on either side. One objection is that the strap is materially weakened at the barbed points by so much as it is cut into.

No. 31.—"Cable" Fencing Wire.—This consists of five No. 14 galvanized wires twisted together as shown in the engraving, which gives a side view, and an end section of the exact size of the sample. It is sufficiently strong to resist breakage by any domestic animals, and will answer well where barbs are objectionable, and the first cost of less account than strength and permanence. It will make a neat village fence. The present cost is 4 cts. per

yard, or 22 cts. per rod for each cable. Manufactured by Philip S. Justice, as per advertisement.

How far and where it may be expedient to use the leading varieties of barbed fencing is still an open question for examination and discussion. Also, which of the various kinds are the best for general use, when any may be used. One thing is pretty well settled, viz.: that none of the long sharp-pointed barbs, having perpendicular sides, or those nearly so, and none of those inclined in any direction to act partially as hooks, are adapted for use along highways or where clothing will be likely to come in contact with them. None of the above barbs are adapted to small inclosures, or where valuable animals are in danger of contact with the long, sharp points of any form. Though they may be so shortened as to remove danger of fatal injury, disfiguring sores and scars will be produced. Something in the form of the "Brinkerhoff Improved," with sides so inclined as to prevent catching and tearing, and so short as not to produce deep incisions when struck squarely, will need to be provided. We understand that the kind referred to is not yet in the market. Whether it is or not, the field is open to inventors and manufacturers, and the public want must be and will be soon met. Hundreds of thousands of land owners, both of farms and village plots—all over the coun-

try, and especially at the West and Southwest—are desirous of changing from wooden to cheaper, more durable metal fencing, and iron posts are included in the demand—those good enough, simple enough, and cheap enough for general farm fences.

## Two Years' Business—1878... 1879.

The following approximate figures are exceedingly interesting, as showing not only the aggregates of several varieties of products, but also the great increase in 1879 over the previous year—1878 itself being in most things a considerable advance over the previous four or five years of depression.

	1878.	1879.	Increase.
Wheat crop, bush.	420,000,000	488,700,000	68,700,000
Corn crop, value...	\$450,000,000	\$600,000,000	\$150,000,000
Hay crop, value...	\$355,000,000	\$325,000,000	\$30,000,000
Oat crop, bush.	43,000,000	364,000,000	421,000,000
Potato crop, bush.	124,000,000	181,400,000	57,400,000
Butter, rec. at N. Y. after Jan. 1, pkgs.	944,100 (?)	1,025,400	81,300
Cotton rec. bales.	4,566,200	4,894,700	328,500
Coal produced.	18,600,000	27,800,000	9,200,000
Anthracite tons.	\$37,876,000	\$31,400,000	\$6,476,000
Gold mined.....	\$37,248,000	\$37,082,000	\$166,000
7011 Gold & Silver	\$74,324,000	\$68,502,000	\$6,822,000
Petroleum export- ed, galts.	329,100,000	402,800,000	73,700,000
20 Railroads, gross earnings.....	\$88,987,000	\$96,557,000	\$7,570,000
Clearing House Exchanges.....	\$32,327,300,000	\$38,912,000,000	\$6,585,000,000

The first four items are estimated, but they are doubtless not far out of the way, the figures in the table being drawn from what is considered good authority, the "N. Y. Commercial Bulletin." The above figures show that during 1879 the business done through the Clearing Houses in a few of the leading cities alone, amounted to nearly thirty-nine Thousand Million Dollars—an increase over 1878 of more than Ten Thousand Million Dollars.

## More Pleasant Figures.

We have before us two full years' reports for the years ending Dec. 1, in 1879 and 1878 respectively. Omitting the specie, we have the following aggregates, in specie values, for agricultural products, manufactures, etc., classed together as

### MERCHANDISE:

12 months ending	Nov. 30, 1878.	Nov. 30, 1879.
Exports from United States...	\$739,895,889	\$751,812,183
Imports.....	430,830,328	455,523,711
Excess of Exports...	\$309,065,561	\$296,288,472
Excess of Exports for two years...		\$575,354,324

That is to say, our country has sold abroad over five hundred and seventy-five million Dollars' worth of its products more than we have imported from other countries. This has been paid to us largely in the form of returned government and other bonds held abroad, and partly by sending us specie, of which we received \$60,239,811 more than we exported, thus—

### GOLD AND SILVER.

12 months ending	Nov. 30, 1878.	Nov. 30, 1879.
Exports from United States...	\$27,322,551	\$25,097,155
Imports.....	28,823,125	86,837,540
Excess.....	(-) \$1,500,574	\$61,740,385

The influx of specie may continue awhile, though temporarily stopped by the speculation in grain which has carried prices above the shipping point. This cannot continue long, for either the foreign demand, when the present stock of breadstuffs is reduced, will raise prices there to correspond with the present prices here of grain and flour, or prices here will come down to a figure at which foreign buyers will take our products. Which event will happen, we cannot of course predict with any certainty. The "probabilities" are that there will be some concession on both sides. High prices will diminish consumption greatly. It may be said, in a general way that, other things being equal, foreign nations would buy and consume twice as much of our wheat if it cost them \$1.25 a bushel, as they would if it cost them \$1.75 per bushel. In the latter case they would much more largely resort to other and cheaper foods. For these reasons the present speculation in grain is to be deprecated. The higher rates benefit the producers very little, and may do them much injury if the result be a failure to find a market for the remaining surplus we have to spare.

## Science Applied to Farming, LIV.

### More about Feeding Stuffs and Fodder Rations.

There are two very important matters connected with the economical feeding of stock which the teachings of modern science explain, but which too few farmers understand, how to adapt the food most economically to the wants of the animal and the purpose for which it is fed, and how to feed so as to make the richest and best manure.

Either the concurrent testimony of the most advanced science and the most profitable practice is false, or the farmers, of our older States especially, must improve their methods of feeding to farm most successfully. For this they need especially to—1st. Produce better foods by better manuring and culture, and by more careful gathering and housing.—2d. Carefully save the poorer foods and waste products, and feed them so as to utilize the large amount of nutriment they contain.—3d. Use a greater variety of feeding stuffs, and in proper mixtures.—4th. Use more nitrogenous foods—i. e., (a) Raise more clover, and, where circumstances will allow, beans, peas, lucern, and other leguminous plants. (b) Buy cotton-seed meal, linseed meal, palm-nut meal, bran, and other nitrogenous foods. (c) Mix these rich materials with poor hay, straw, cornstalks, and the like, in such proportions as are fitted to the wants of the animals and the purposes for which they are fed. This will bring excellent fodder and rich manure at very low cost. To see why these facts are so, note the table below.

Nutritive Ingredients of Foods and Feeding Standards.

FOODS AND FEEDING STANDARDS.	DIGESTIBLE FOOD INGREDIENTS.				Nutritive ratio.

### Rich vs. Poor Foods—Proportions of Digestible Albuminoids, Carbohydrates, and Fats.

Now let us take a poor food, as oat-straw, and compare it with good hay. One hundred pounds of “very good” hay contains about 50 lbs. of digestible material, while the same amount of oat-straw furnishes some 42 lbs. At this rate, 120 lbs. of oat-straw would supply as much nutritive material as 100 lbs. of first quality upland hay. But it would not be worth as much for fodder. Why the straw is worth less appears when we compare the amounts of the different ingredients. The 100 lbs. of hay, with its 50 lbs. of digestible matters, fur-

nishes 7.4 lbs. of albuminoids against only 1.4 lbs. in the straw. So likewise the hay contains 1.3 lbs. of fats, the straw only 0.7 lbs. But when we come to the carbohydrates we find just about the same amounts in both. The straw lacks albuminoids and fats, and these are the most valuable ingredients of the food. The albuminoids make all the nitrogenous tissues of the body, the lean meat (muscle), the gristle, skin, etc., all the albumin and casein of the milk, and part of the fat of the body and of the milk (butter), besides sharing in the production of animal heat and muscular force. The fats of the food are transformed into fats in the body, and share in the production of heat and force. They can not be made into muscle or other nitrogenous tissue, however, because they have no nitrogen. At least, the present evidence is entirely in this direction. The carbohydrates do not make nitrogenous tissue in the body. They are probably transformed into fats, but only to slight extent. They serve for fuel, and seem to aid in producing muscular force. They thus do a work of their own, which, if it were not for them, would be left for the costlier albuminoids and fats. So even if the carbohydrates are not made into flesh, fat, butter and casein themselves, they doubtless do what amounts in practice to the same thing by saving the other ingredients to be used for these purposes. Starch and sugar are carbohydrates, but they are at the same time valuable foods.

The reason for the inferior worth of the straw may be seen from another standpoint in the last column of the table, “Nutritive Ratio.” The “very good” hay has 1 lb. albuminoids for every 6 lbs. carbohydrates (1 lb. fat being reckoned equal to 2½ lbs. carbohydrates), while the straw has one pound of albuminoids to 30 lbs. of carbohydrates. According to the feeding standards, for a milch cow a ration with 1 lb. albuminoids to 5.4 carbohydrates will be appropriate, while an ox at rest in the stall will do well with only 1 lb. albuminoids to 12 lbs. carbohydrates. The best hay will serve well for making milk, while the straw has not enough of the albuminoids and fats to make it a proper food for even store cattle. There is a great difference between

### Good and Poor Hay.

Upland hay cut during the period from early blossom to full blossom is easily digestible, and has a good percentage of albuminoids. But as it grows older the proportion of nitrogen decreases, and that of woody fibre grows larger, the hay becomes less digestible, the digested material is poorer because it lacks albuminoids, and finally the old hay is not so palatable. For all these reasons the late cut hay is worth far less for feeding. Grass grown on rich soil is richer in albuminoids than on poor soil. Marsh and bog hays lack albuminoids and fats. Clover, timothy, red-top, blue-grass, and the like, grown on good soil, cut early and well cured and housed, make excellent fodder. Poorly manured, cut late, and badly cured, they are very poor stuff. Much of the hay that lies in the barns all through the country is very little better than straw.

### The Way to Use these Poor Foods

economically then must be to supply what they lack. To make boots of neck or split leather, or to throw the poor leather away, would be bad economy. With good leather for the parts where the wear comes, the poor leather may be used for backs and linings, and thus be made valuable. So we may feed straw, corn-stalks, and over-ripe or marsh hay to advantage, provided we put other foods with them to supply the albuminoids and fats. Now note in the table the figures for clover, bran, beans, peas, oil-cake, meat-scrap and dry ground fish. They have very little carbohydrates, but are rich in albuminoids and fats.

### Cotton-Seed Meal, Linseed Meal, Palm-Nut Meal, and Bran,

are foods whose value farmers in this country are just beginning to appreciate. European farmers long since found out how much they are worth, and thousands of tons of American oil-cake and meal have been carried across the Atlantic to enrich English, French and German foods and soils. The time has come when we must keep them at home if we are going to redeem our farming. The great value

of these foods is due to two facts. First, they supply the albuminoids and fats in which poor hay, straw, corn-stalks and the like are lacking. Second, they make rich manure. How they may be used with poor foods to make good rations at small cost is illustrated in the fodder rations in last month's article. Chemistry indicates, experiments prove, and experience corroborates the principles that poor foods, as late cut hay, marsh hay, straw, corn-stalks, etc., can be utilized and made very valuable by feeding with them nitrogenous foods such as oil-meal, bran, and clover hay, to supply what they lack. It is proved that such mixtures make the very best rations; and still further, that this is one of the cheapest ways to get good manure.

### Dried Blood, Meat Scrap and Fish as Food for Stock.

Years ago, oil-cake used to be employed as a fertilizer. Chemistry said it ought to be first fed to stock, that it has a high nutritive value, that in going through the animal machine but little of the valuable material is consumed, and that the residue is worth more for manure than before. Experience proved that all this is true, and now nobody would think of using linseed-cake or cotton-seed meal for manure. Of late, immense quantities of slaughter-house refuse, dried blood, dried intestines, and the like, and still larger quantities of the refuse left after the extraction of oil from fish, are being prepared and used as fertilizers. These ought, like the oil-cake, to be first utilized for food. The idea, though novel to most farmers, is an old one, and has been put into successful practice in many places. In its favor is the unanimous testimony of chemical composition, careful experiments, and the experience of farmers who have used the materials with success. Against it are, the difficulty of preparing wholesome materials, which can be overcome, and the prejudice that only time and trial are needed to dispel.\*

### The Manurial Values of Nitrogenous Foods

is a matter worthy the thoughtful consideration of farmers. Nitrogen, Phosphoric Acid, and Potash are the most valuable ingredients of manure. Farmers buy them in the better kinds of commercial fertilizers at the rate of from fifteen to thirty cents per pound for nitrogen, six to eighteen cents per pound for phosphoric acid, and three and a half to nine cents per pound for potash. Cotton-seed, linseed, and palm-nut meals, bran, dried blood, meat-scrap, and fish, are rich in these ingredients. Mr. Lawes has made some calculations of the money values of the manures produced from different foods. This he does by assuming that certain percentages of nitrogen, phosphoric acid, and potash are consumed and lost, that the rest go into the manure, and that they have there about the same value, pound for pound, as similar ones in commercial fertilizers in which their value is pretty well settled. I give Mr. Lawes' estimates of the value of manure from a number of foods, and with them the feeding values, as estimated by Wolff, per table in December *American Agriculturist*, page 497.

FEEDING VALUE.		MANURIAL VALUE.	
Wolff.		Lawes.	
Cotton-seed Cake .....	\$41.40 per ton.	\$27.86 per ton.	
Linseed Cake.....	34.40	19.72	
Beans.....	15.20	15.73	
Wheat Bran.....	20.80	14.59	
Clover Hay.....	14.00	9.64	
Indian Meal.....	22.20	6.63	
Meadow Hay.....	12.80	6.43	
Oat Straw.....	9.00	2.90	
Potatoes.....	5.80	1.50	
Turnips.....	2.20	.86	
Meat Scrap.....	55.60	—	
Dry Ground Fish.....	46.00	—	

Mr. Lawes rates the ingredients pretty high and probably allows too little for loss in passing through the animal and in the keeping and handling of the manure. Wolff's rates doubtless require modification for our markets, and the actual worth of the nitrogenous food stuffs would come up to the valuations only where they are properly used with other foods.

W. O. ATWATER.

Wesleyan University, Middletown, Conn.

\* For discussion of the subject, and accounts of numerous feeding experiments with these materials, see article on *The Agricultural Uses of Fish*, in Report of U. S. Fish Commission for 1877, and in “*American Fisheries*” (Orange Judd Company, New York, 1880), page 258.

## Farm Buildings Costing \$3,000, Complete.

BY S. B. REED, ARCHITECT.

These plans are for compact, convenient and economical farm buildings. The arrangements are similar to buildings on the farm of Mr. Geo. Thorpe, in East Meriden, Conn., with some modifications to

Fig. 1.—FRONT ELEVATION OF HOUSE, SHED, AND BARN JOINED TOGETHER, AND COSTING \$3,000.

meet the more general requirements. There are several objections to having all the principal farm buildings joined together, such as the increased danger from fire, health, offensive odors, flies, dust, and filth, when the barn and house are too close to each other. The buildings shown, fig. 1, with 1st and

Fig. 2.—CONDENSED PLAN OF THE BUILDINGS.

2nd stories condensed in figs. 2 and 3, are well adapted, if preferred, to be erected at a distance from each other. The owner in this case considered all the objections, and concluded that they could be overcome by an intelligent arrangement of the several parts, covering all by increased insurance (which

Fig. 3.—SECOND STORY AND LOFT CONDENSED.

would be essential in any case), and also exercising a proper carefulness in management. He claimed that for all this, he would be fully repaid by increased convenience, especially as the unevenness of the adjacent grounds made it desirable to have the buildings on a limited space. . . . **Site.**—The grounds are slightly inclining to the right, and ending at a brook of running water at a short distance. Having a southward frontage, the north

Fig. 4.—FIRST STORY OF HOUSE.

winds are shut off from the yards and principal entrances. In preparing for the building, materials and forces already on the farm were utilized, and the excavating, grading, getting out stone, hauling materials, building the foundations, dig-

ging well, etc., were done at odd spells, so that, excepting the wages of a stone-mason, the cost of these parts was scarcely felt. . . . **Dwelling.**—The *Cellar*, 6½ feet in clear height, extends under the whole house, with foundations showing 2 feet above ground. The *First Story* (fig. 4), has ceilings 10 feet high, and contains a hall, five rooms, and a pantry. The living-room is the largest, with outside doors and windows front and rear, and communicates directly with a work-room, front hall, and the cellar stairs. The work-room is used as a "scullery" and entrance way from the shed, and from it a private stairway leads to the second story.

The parlor, at a distance from the working and living-room, has a bay-window in front, and a plant-window at the side. The hall is entered from the front porch, and contains the main stairs, with the cellar stairs underneath. . . . **Second Story** (fig. 5); ceilings 8 feet high in the main house, and 4 to 8 feet high in the wing. It has eight sleeping rooms, a hall, passage, and six closets. The hall and passage join through a door, which may be fastened to cut off all communication between these parts when desirable. The stairs to the attic are over the main flight. The attic is floored, and provides good storage room. . . . **Barn.**—The foundations may be of stone when accessible, laid in trenches below the reach of frost, and the outside walls carried up to 3 feet above ground. All stone-work above ground is faced and pointed on both sides. This unusual height of the foundations above ground insures increased warmth to the interior, and prevents decay of the wood-work above. The main sills are laid flat on the stone-work, and thoroughly embedded in mortar, preventing entrance of air or moisture at the joinings. The height of the principal frame is suited to the use of 16-foot tongued and grooved vertical boarding—this, added to the 3 feet of foundation, gives sufficient height for practical use. The central space (fig. 6) has large doors at each end, admitting hay loads from front or rear. Head-lights over these doors give light to the interior when the doors are closed.—The cow-stables are 7 feet high, and are placed at the farthest distance from the dwelling. The two horse stalls are 8 feet high. If others are wanted, they can be taken from the bay. All stables and stalls are tightly floored above to prevent dust from sifting through from the hay-loft. . . . The **Cattle Shed** (only partly shown).—The rear and end foundations are of stone, the same as the barn. The open or lower portion is 8 feet high, with fodder-racks and mangers along the side. A door in the side leads to the grounds at the right. The upper portion is 4 feet high at the plate, has a door opening to the yard, and is floored for a hay-loft. . . . **Wagon Shed.**—The foundations correspond with those of the dwelling. The lower portion is 9 feet high—sufficient for top-carriages. There is space for a wagon and feed-bins, besides leaving a covered-way from the house to the barn. The entire front is unobstructed,—a strong truss supporting the upper part. Flap-doors at the rear, swinging upwards, give summer ventilation. The upper portion, floored over, and lighted by six small windows, answers for a repairing and storage-room. A trap-door in the center (fig. 3), and a strong hook for tackles, in the ridge above, facilitate lifting heavy articles. Sleighs, wagons, hay-rakes, plows, or any farm utensil may be easily raised to the shop for repairs or storage. . . . **Cost.**—The following *Estimate* of materials and cost is given separately for the principal parts. Everything is plain and substantial.

### DWELLING ESTIMATE.

100 yards excavation, at 2 c. per yard.....	\$ 20 00
1,400 feet Stone-work (complete), at 8c. per foot.....	112 00

## The Angus Polled Cattle.

The engravings on this page are portraits of some Angus Polled cattle, popularly known as "doddies," bred by Mr. Thomas Ferguson, of Kinnochtry (Kinnochtry), near Conpar-Angus, Scotland. We have a full account of this famous Kinnochtry herd, sent by Mr. Alexander Ferguson, the son of Mr. Thos. Ferguson, and we regret we can find space for only a short transcript of his extended article. Mr. F.'s herd was started in 1835, and since then has been under a course of constant improvement, until it is now a model herd of these useful and much esteemed cattle. The growing popularity of the polled breeds in the United States is to be noted not only among breeders, and graziers of beeves, but dairymen are losing their prejudice in favor of the dangerous and injurious horns, and are more and more favorably inclined towards polled animals. A remarkably graceful and beautiful polled cow, a cross between a polled bull and a Jersey cow, was exhibited at the last N. J. State Fair, and attracted much attention. It is unquestionable that a useful, docile, and harmless race of cross-bred dairy animals might be produced by crossing our best native cows with polled bulls from cows selected for their milking qualities. The polled cattle have been bred long enough to thoroughly establish their peculiarities; and their propensity is so strong as to stamp their hornless character upon their progeny with almost unfailing certainty. That a large majority of the calves got by polled bulls are also polled, has already been proved by the successful experiments of the late Mr. Grant, of Victoria, Kansas, from whose herds polled grade steers have already come to market.

The Kinnochtry herd owes some of its excellence to that of Mr. Hugh Watson, of Keillor, a farm near to Mr. Ferguson's, where Mr. Watson had been engaged in improving the breed since 1808. The Keillor herd is noted for producing "Old Grannie," a cow which lived 35½ years, and produced 25 calves, 11 of which are registered in the Polled Herd-book. She milked up to her 29th year, when she ceased breeding. "Old Grannie's" last calf, a bull, "Hugh," was used in the Kinnochtry herd, and bore a striking resemblance to "Shah," the subject of our portrait. The immediate progenitors of this herd have a direct and close ancestry for 111 years, tracing back to the original source of Mr. Watson's Keillor herd. This herd has thus the oldest and best blood in existence, and numerous prizes have been secured by animals of this strain, from that gained by "Old Grannie" at Perth, in her 6th year, up to the first prize at the Highland Society's Show in 1873, taken by "Shah," who was exhibited after having served more than 60 cows during that summer. At the exhibition of the National Society of Ireland, in 1879, all the prize

polled animals were the produce of Kinnochtry bulls; while the prizes directly taken by members of the Kinnochtry herd number several hundreds. These cattle are accustomed to a bleak climate, and may, therefore, be expected to be hardy; but their natural vigor has also enabled them to survive and thrive in the West Indies, where, after having witnessed the failure of Shorthorns, Herefords, and

of great value, and so soon as a few enterprising dairymen have, by successful breeding and use, removed the baseless prejudice against black and hornless cattle, we look for an extended introduction of polled cows into our dairies. These cattle, at least the strain under notice, have been closely but very skillfully and successfully in-and-in bred, and to this their excellence and uniformity of type

are due. Such stock may be made to take on any character we wish, and it will be as easy to make dairy cattle of them, as beeves. The polled head should be the "trade mark" of the dairy, as it may now well be taken as that of the grazier of beeves. The handsome figure of the heifer, a "Favorite," daughter of "Favorite 5th," coming 3 years old, as shown by our portrait, is that of a model cow; she gained first prize at the Strathmore show in 1879, and her heifer calf is said to be remarkably promising. It is a model cow, not for the dairy, we admit, but for a square, massive, symmetrical beef animal, will rival the best of the Shorthorns. We here repeat, these animals are plastic in the breeder's hands, and may be made excellent for use in other ways than for beef. Dairy products are as indispensable as beef, and it certainly seems desirable that the good qualities of the polled breed should be turned to account in both the dairy and stall.

## Among the Farmers.—No. 49.

BY ONE OF THEM.

If I make out to break away from my little farm and from the routine of business, I am expected to tell the *American Agriculturist* readers about it.

### The Massachusetts Butter Show.

An urgent letter from my old friend, James S. Grinnell—a most active man in all that affects the agriculture of Franklin County, as well as in many other good things, and who honors the position of President of the Agricultural Society of that County—decided me to go to the first State Butter Show ever held in Massachusetts. The movement for a show originated with Mr. Grinnell and Major Alvord, of East Hampton, and it was certainly a great success, as well as an instructive and interesting occasion. The time selected was when the winter meeting of the Mass. Board of Agriculture is held, butter was shown, and dairy subjects discussed in the meetings. The show was not only one of butter, but of butter-making apparatus, of which there is a large variety at every such exhibition. Among other useful things, those which most interested me were

### Mr. Bond's Centrifugal Machines,

and Mr. Burnett's statements of his success in the daily use of the only one, a "Weston" machine, which has been put to the test of practical use in

Fig. 1.—ANGUS OR POLLED BULL "SHAH."

Ayrshires, a Polled Angus bull still remains healthy and vigorous after several years residence in that hot climate. In short, there is no doubt of the usefulness and value of this breed of cattle, in their own home and in other countries. It remains to be shown that they can be made both useful and profitable here. For the production of beef they stand ahead of all, even of the vaunted Shorthorns. Of this there is no question. The absence of horns renders them inoffensive and harmless to other cattle and safe with their keepers; besides giving them an economical value in the

Fig. 2.—ANGUS HEIFER "FAVORITE."

market, on account of their more easy carriage. For the dairy they promise equal advantages. They are fair milkers, as they now exist, with all their aptitude for taking flesh and fat, and the milk is remarkably rich in butter. For crossing upon our large milking native cows they are considered to be

this country. Rev. Henry F. Bond, of Northboro', Mass., has the merit of applying the principle of centrifugal force to the separation of milk and cream as an original inventor. It does not detract from this merit, but only from the profits likely to be derived from it, that the invention had been anticipated in Europe by a few months, nor that an American inventor and maker of centrifugal machines had patented a process ten years before for separating oils and pigments of differing specific gravity, which is applicable to this same purpose. [Our correspondent has been misinformed as to dates. We have a French work, printed in 1872, which describes a centrifugal chnrrn, and we give in another article, engravings from another French work, without date, but which describes the machine of Maj. Sterjnsvard, of Sweden, to which was awarded a prize at the Paris Exposition, 1855! Ed.]

Mr. Bond was kind enough to narrate to me in detail the steps by which he arrived at his interesting results, and I think they are worth recording. The idea occurred to him, one day, that this force, which causes all things, made to revolve rapidly in a circle, to tend to fly off away from the center of that circle, acting as it does upon all bodies in proportion to their weight, and incremable indefinitely, might be applied to "raising" cream. After some consideration he called upon a friend and neighbor, Mr. G. F. Windsor, the proprietor of a creamery, and who had machinery which could be used for a test. The first experiment consisted in attaching strong wire bails to two glass fruit jars, holding two quarts each, and suspending them, nearly filled with fresh milk, upon opposite sides of a band wheel revolving upon a perpendicular shaft. Motion, with increasing speed, was gradually given to the wheel and the jars as gradually assumed the horizontal position. After two hours they were examined and the cream found to be entirely separated, and in a firm, solid mass, quite free from milk, so that it could be taken out by the hand as a lump. As to time, it was found that the results at the end of one hour's whirling were quite as good, and that fifteen minutes even served to effect a complete separation.

Large vessels holding 16 to 18 quarts, made of tin, but very much strengthened, were tried, but the force was found to be far too great. The vessels collapsed, and one flying off, caused the other also to be wrecked almost instantly. Fortunately, the gentlemen had taken the precaution to

Fig. 1.—MR. BOND'S FIRST EXPERIMENT.

go to the floor above to watch and regulate proceedings. As a direct result of these experiments we have Mr. Bond's machines. An idea may be had of their general form, by placing one tea saucer inverted upon another one. They were small affairs of copper, which Mr. Bond exhibited, one adapted to taking a charge of, say a gallon of milk, and in fifteen minutes completely separating the cream, but it was not provided with any means for drawing off the cream and the skimmed milk, while in motion. The other was arranged either to maintain a constant flow of the two separated products while the milk was flowing in, or to draw off the milk at intervals, while the accumulation of fluid in the revolving vessel caused an overflow of cream.

At first, a little difficult to get the idea of the

action which takes place in these machines, and yet it is just as simple as the raising of cream in a pan or other vessel. Take, for instance, the simplest form alluded to—a vessel shaped as in fig. 3, filled to the line, *m*, with milk, and made to whirl by a band upon the pulley, *p*.

The first obvious effect will be a depression of the milk in the center, as shown by the dotted line; then this will increase with the speed, until the milk has a position as far from the center as it can get, as shown by figure 4: *m*, being the surface of the milk, now forming the walls of a perpendicular (hole) cylinder, the shaded part being the milk. It is clear that if the heaviest fluid goes farthest from the center, then the milk will, after a while, settle at the outside, while the inner wall will consist of cream.

The next problem for the inventors was, how to secure the products thus separated, as they would mingle again, were the motion to cease and gravity

Fig. 3.

again act and bring them to a level within the vessel. This has been solved in one way by the Swedish inventors, in another by the Danish mechanic, who has brought out one of his machines, in still another by Mr. Weston, and in two or three different ways by Mr. Bond. A difficulty which has to be encountered, and which has probably not yet been successfully met, is this: that the cream driven off at such a high rate of speed as 1,200 or 2,000 revolutions to the minute receives damage, in that the butter globules are broken, more or less, so that, as Mr. Burnett intimated at the meeting, the cream was half churned. It is, however, perfectly good for use as cream; but it may be a question whether the butter made from it will be of such high quality as if it were raised in the usual way. This is then the problem, in the solution of which the interest now centers. Mr. Burnett stated also that a green sediment, heavier than the milk, was found to adhere to the walls of the Centrifugal, and this, on examination, proves to be minute organisms inherent in the milk, and a probable chief cause for souring and the setting in of that series of decompositions which milk so rapidly undergoes at a high temperature. The separation of this matter is highly important and advantageous.

#### Other Dairy Appliances.

There was a good deal of improved dairy apparatus exhibited, including several new arrangements for setting milk. Improvements in the "Cooley" system, the Furguson "Bureau" system, Moseley & Stoddard's "Cabinet" system, etc. The Dairy Supply Co. showed their "Perfect Milk Pail," the Nesbit & Rapp Butter Presses, which were new to most of the people, and a number of butter packages. Several new churns were shown, among them, and the newest of all, is one made by Mr. Bullard, whose oscillating churn has been highly approved. This consists of a tub balanced upon an upright rod, and made to swing round and round, guided by an iron ring, of a little less diameter than the tub. Two breakers within the tub cause the cream to dash from side to side. It is a novel affair.

#### The Butter.

There were 119 entries of butter placed in competition for the liberal prizes offered. It was generally presented in ten-pound boxes. The committee seemed to have no difficulty in deciding which sample was unequivocally the best, but a good deal of trouble in adjusting the awards, depending upon

Fig. 2.—TWO SAUCERS.

the mode of setting, kind of salt used, etc. The award of the first prize and sweepstakes, altogether amounting to some \$125, or \$130 as I am informed, developed the fact, that the recipient, Mr. Chas. E. Fisk, uses the "Perfect Milk Pail," and so far as I could learn, he was the only one who uses it of the whole 119. If any of the other competitors use a pail which excludes the atmosphere of the stable, it would be interesting to know it.

#### The Addresses and Discussions

were of a valuable character, developing a good deal that was new to me. Prof. Goessmann, of Amherst, stated the results of some recent analyses and investigations of corn-cobs, showing that they have a far greater nutritive value than have usually been attributed to them. In Mr. Grinnell's sketch of the agriculture of Franklin Co., he showed that the lack of railroad facilities had caused a diminution of population of from 15 to 50 per cent in some towns, while the general population of the county had increased largely. The disuse of fences seems to be greatly on the increase in Massachusetts. Mr. Grinnell pointed out to me the farm, where the road forks at the head of Greenfield Street, on which he was born, and still in possession of the family, and worked by himself, whereon there were no fences at all, not even along the highways, except surrounding and perhaps dividing one large pasture lot at a distance.

#### Milk and Cows.—What Chemists Say.

The last Report of the Secretary of the State Board of Agriculture, of Michigan, contains a paper on "The Analysis of Milk from Different Breeds of Cows," by R. F. Kedzie, Assistant in Chemistry at the State Agricultural College, from which we condense some of the most interesting features. To test the influence of temperature on the rising of cream, three pans of milk in every way alike, were kept at the temperature of 32° F. 55° to 60° and 75° to 80° respectively, for 24 hours. The cream was then removed from each pan, and the amount of fat remaining in the milk determined.

Kept 24 Hours.	Fat—Per Cent.
At 32°	1.25
At 55° to 60°	.59
At 75° to 80°	.79
Fresh milk.	3.26

Professor Kedzie's conclusion is, that 50° is the best temperature at which milk should be kept.

With the cooperation of the Professor of Agriculture, a series of experiments was carried on to determine the influence of food upon the quantity and quality of milk. While upon poor food the cows received 5 pounds cut cornstalks, 2 pounds cut oat straw, and 2 qts. of a mixture of two parts Indian corn meal and one part shorts, twice a day. During the period of high feeding the same cows, grade Ayrshires and grade Jerseys, received the cut feed as before, to which were added, 40 pounds of sliced turnips, and 6 qts. of mixed ground feed per day. The amount of milk was much increased, while the percentage of milk elements remained much the same. "If a large amount of rich food is given, a part of it goes to increase the number of quarts of milk, and the rest to the increase of fat in the animal."

The following table of averages of the different breeds, deduced from a large number of milk analyses we reproduce in full:

Name of Breed.	Sugar. %	Caseln. %	Fat. %	Water. %	Ash. %
Shorthorn....	3.76	4.41	5.10	86.04	.68
Ayrshire....	3.90	5.08	3.75	86.57	.70
Jersey.....	3.76	4.37	6.87	84.28	.71
Holstein....	4.35	4.21	6.84	83.97	.61
Galloway....	3.80	5.36	3.40	87.43	.67
Devon.....	4.23	5.29	3.96	85.71	.81
Grade.....	4.29	4.99	4.01	85.92	.79
Native.....	4.08	5.21	3.36	86.64	.71

From this table we see that the Holsteins stand at the head for fat, or butter, and the Jerseys next, while for the production of caseln—cheese—the Ayrshires lead, followed next by the Natives. It is to be remembered that this is looking at the subject from a purely chemical standpoint, and it is for the practical dairyman to determine how much it

Fig. 4.

costs in food, care, etc., to produce a given amount of butter, or cheese, in each case, and whether the products of different breeds, pound for pound, are of the same market value.

### A Nose Jewel for Sucking Calves.

C. A. Thresher, Topeka, Kans., sends a description of an improved nose jewel for a sucking cow or calf, which can not slip out of the nose. Usually

NOSE JEWEL.

these are so made as to slip over the septum of the nose, and if they are so loosely fitted as to be slipped on, they may be forced off by the efforts of the animal with equal ease.

To prevent this, Mr.

Thresher suggests making one of the points loose and fitting it to the lower part by two screws, as shown in the engraving. It can not then be removed from the nose without first taking out the screws. The board should be of hard-wood, half or three-quarters of an inch thick, and may be cut out of the proper shape with a key-hole saw. The holes for the screws, 2 inches long, are then bored, and the point sawed off. There is no need to take out both the screws when fitting the board to the nose; one screw may be drawn and the point of the "Jewel" turned partly around, to be returned when fitted, and the second screw may then be put in its place and all made secure by turning it home.

### A Gate Without Hinges.

A very convenient gate is here described, which, having no hinges, and not being made to swing, can be used in deep snow, as conveniently as when the

Fig. 1.

Fig. 2.

ground is bare. A latch post is fixed in the ground, and connected with the fence. This is upright as shown at figure 1, and is made by nailing a piece of narrow batten to a square post, and then a piece of fence strip to the batten, so as to leave a slot on the side of the post, from the top to the bottom, in which the ends of the gate bars fall, when it is closed, as at figure 3. A heel post is set in the ground, and slopes backwards, as seen at figure 2.

Fig. 3.—THE GATE DOWN.

The gate is fitted to the heel post by bolts, as shown at figure 3. The gate is made in the following manner. The five bars are laid close together upon a level floor. These may be of fence strips, or battens 3 inches wide, and one inch thick. The place for the lowest hole, at *a*, being chosen, the aggregate

width of all the bars being added, an equal distance is laid off, as from *a* to *b* on the lower bar, and a line parallel with the ends of the bars at the front, is marked on the bars, as shown by the dotted line *b, c*. The upper hole is then made at *c*, and the two binding pieces are fitted, as shown in the accompanying engraving, by carriage bolts, which should work easily in the holes; the ends of the bars being kept even, as in the engraving. The lowest bar may be four feet long, which will be a convenient length for a hand gate. The rear strip is fitted parallel to the front strips, and with the bars is bolted to the heel post. The top bar is 7 feet long, and has a weight hung to the end, which nearly balances the gate, so that it may be swung up, as shown at figure 4, with but little effort, when the balance weight is sufficient to keep the bars raised. For winter use, this gate is a very desirable one.

Fig. 4.

### Ergot and Abortion in Cows.

An interesting account of the growth of Ergot, or "Spurred Rye," as it is often called, is given in the "Live Stock Journal," (Eng.), for Oct. 31st., by Prof. Henry Tanner. In the illustrated article on Ergot, in our October number, page 388, and also in previous articles on these destructive pests, it was shown that moisture is necessary for the development of most fungi. In England and throughout Europe generally, the past season has been remarkable for its abundant rains, and, as a result, we should expect an abundance of Ergotized grain and grasses. Such is the case, and as a sequel, to quote the Professor: "We regret to notice that the last few months have been more than usually remarkable for abortion among cows." The question of prevention is a serious one, but it can be satisfactorily answered by not allowing cows to run in pastures where the grass has gone to seed. The Ergot appears only in seed, and is an abnormal development from the substance of the seed; while the grass in the pasture is without seed-bearing heads there is no danger. The seed-stems standing about these fields, are so many danger-signals to the stock-master, who knows the liability to this production of Ergot. The scythe should be used to cut down any places in the pasture, where the grass is "running to seed." The lesson taught by the wet season abroad, is an important one for our people in its relation to the excessive production of Ergot, and the prevalence of abortion among cows.

**Corns on Horses' Feet.**—Corns are rarely absent from flat-footed hoofs. They are caused, in the majority of cases, by stones lodging in the space unwisely left by blacksmiths between the inner edge of the shoe and the sole of the foot, as shown in the engraving, which represents a section of a shod hoof. This causes a bruise, which soon becomes inflamed, and the horn being unyielding the products of the inflammation can not escape, and remain as a constant source of tenderness and pain. The remedy is to keep the space stuffed with tow soaked in glycerine, or otherwise to lay a leather sole under the shoe to protect the sole of the foot.

SECTION OF HORSE'S FOOT.

The products of the inflammation can not escape, and remain as a constant source of tenderness and pain. The remedy is to keep the space stuffed with tow soaked in glycerine, or otherwise to lay a leather sole under the shoe to protect the sole of the foot.

**Does it Pay to Winter Turkeys.**—The general practice in the poultry districts is, to fatten the early broods of turkeys for Thanksgiving and

the later ones for Christmas, and to send each lot to market in a lump. The advantages of this are, that the warmer weather of autumn is favorable for fattening, and less food is consumed. The money also comes in a pile, and much labor is saved. But occasionally we find a farmer who feeds his turkeys straight on through the winter, selling in small lots, when he can get his price. When we ask him for his reasons, he tells us that there is always a difference in selling farm produce at the buyer's price, and in selling it at your own price. The turkey crop is mainly disposed of at Christmas—and he can always get a better price if he waits until February and March. The turkeys are all the while growing, and are wanted in the village markets at reasonable paying prices. There is also a good demand for them as breeders in March and April. It pays him to winter his flock.

### Inside Fastenings for Barn-Doors.

"A Reader" asks us for some good methods of fastening barn-doors from the inside. In the Nov. number, 1877, an illustration was given of a fastening, which may just meet the case, and as this question is of general interest, the cut is again used; we present it with two other methods which have the recommendation of long, and quite general use, rather than newness in their favor. In figure 1, the bars, three in number, are made of hard-wood, 1½-inch thick, and 3 inches wide. Two of these are made to slip loosely through iron staples, driven into the batten of the door, and are joined in the middle by a bolt. A third and shorter strip, the "guide," has its upper end fastened to the other two, by the bolt above mentioned, while its lower end is secured to the door by a screw, in the

Fig. 1.

Fig. 2.

position shown in the engraving. The working of the fastening is easy to see. When the two long bars are upright, as shown by the dotted lines, their ends pass above the door, and into mortises in the ceiling and floor, and are held in place by the guide. By pushing the middle part of the fastening to the left, the ends of the bars recede from the mortises, and the door is free to be opened. Aside from the secureness of the fastening, it is always in place, and very easy to operate. In figure 2, a much simpler method is shown, which consists of a single, long, hard-wood bar, a little longer than the door, and fastened to the middle batten by a bolt. The ends of the bar pass into slots cut in the beam above, and the floor below. The upright position of the bar in the engraving, shows when the door is fastened, and the dotted line indicates where the bar is pushed, when the door is opened. In working this fastening, the bar is grasped by the hand above the bolt, and one foot is used to push aside the bottom.

Fig. 3.

A third form of inside door fastening, is given in figure 3. This consists, as the engraving plainly shows, of two upright bars, fastened in the middle

to a lever, one on each side of the point, and the lever is bolted to the door. The other ends of the fastening-bars pass through blocks of wood, cut to fit and nailed to the door. The fastening is at the top and bottom, as in the other two methods, the bars being moved out of and into the mortises, by the long lever. The door is shown fastened, and the lever is downward; the dotted line gives the position, when the bars are withdrawn from the mortises and the door is ready to be opened.

### Hints and Helps For Farmers.

**HOW TO PUT UP A WAGON BOX.**—To get rid of the cumbersome wagon box, or bed, is an in-

Fig. 1.—WAGON BOX ON A SHELF.

teresting question for those who have not much shed room to spare. The most convenient way is to hoist it up over head in the manner described in the *American Agriculturist*, Sept., 1875; but the easiest and cheapest method of disposing of it is as follows: To the side of the wagon shed, fix two strong bars supported by braces, as shown in the engraving. The wagon is driven close to these, the hinder end of the box is lifted off from the wagon, and the forward part swinging around, permits the end to be placed on one of the bars. The forward part is then lifted upon the bar, and the job is done in about as short a time, as it can be described; and furthermore, one man can do it alone.

**A GATE WITHOUT HINGES.**—A subscriber in Pennsylvania, sends a description of a gate, which is without hinges. It turns upon a pin, of 1½-inch round iron, fixed in a block of wood or a stone, under the heel-post, and a pin bent to a proper shape, fitted in the top of the heel-post, as shown

Fig. 2.—A GATE WITHOUT HINGES.

at figure 2. This method of hanging a gate is cheap, simple, and more secure, than to use hinges.

**NON-FREEZING PUMPS.**—A mute but very eloquent expression of disappointment, is frequently given on a cold morning by a number of thirsty cows standing around a water trough, and a pump solidly frozen up, while their owner is vainly trying to thaw out the pump, by pouring hot water into it from a kettle. If those thirsty cows could speak, they might give some good advice to their thoughtless owner, but it is their fate to suffer and bear such disappointments, without power of remonstrance. We will offer a little suggestion, as to how the trouble may be avoided. In the best pumps,

such as the "Universal" and others which are continually brought to notice in our business columns, provision is made to avoid freezing up in cold weather. While the "Submerged" pump, being entirely under water, can not freeze, unless ice forms at the bottom of the well. Some farmers are not so fortunate as to possess anything better than a common wooden pump, yet even this may be arranged in a simple manner, so as to be always in working order, in the coldest weather. Remove the covering of the well, and bore a half-inch hole in the pump-tree, 2 feet below the surface of the earth. In this hole, insert a tube of elder wood, with the pith removed (fig. 3). When the pumping is done for the time, the water which is left in the pump, will escape from the tube, and freezing will be prevented.

Fig. 3.—NON-FREEZING PUMP.

**POULTRY FOUNTAINS.**—"J. H. S.," Quincy, Ill., recommends a simple water fountain for poultry. This, (fig. 4), consists of a common stoneware jug, which is filled with water, and inverted in a basin, or wooden trough. A peg may be fixed in the trough so as to enter the mouth of the jug, and prevent it from being pushed to one side. Four stakes driven in the ground, or otherwise arranged, so as to keep the jug always in its upright position.

Fig. 4.

**A WESTERN HAY GATHERER.**—It must not be supposed, that in the great wheat growing regions of the northwest, grain only is produced. The fact is, that those vast prairies are magnificent grassy meadows, which in places yield as much as four or five tons of hay per acre. It is here where the "Blue-joint" (*Calamagrostis Canadensis*), so well known in the broad "beaver meadows," and river-flats of the Northern, and Western States and Territories, flourishes so luxuriantly; and this grass, when cut in good season, is found to be equal to the best of our cultivated grasses for hay. A large quantity of this hay is cut every year, and put up for the purpose of supplying the numerous teams employed on the enormous wheat farms which are now worked in the localities referred to. Cheapness of operation is a marked necessity in doing business in a large way, and the hay cut upon those broad prairies, is put up for about one dollar per ton. The method of working, is as follows: The grass is cut by mowing machines, and as it rarely rains, the cutting goes on steadily until sufficient has been laid down. A rake is then employed to gather, and carry it to the stacks. The implement used, is a long frame, which is drawn upon runners, as shown at figure 5, and is made of a principal bed-piece or sill to which the runners are fastened. Side posts are fixed to the runners, and these are connected by cross-bars which confine the hay. Long rake-teeth are inserted in the bed-piece, and these gather up the loose hay, which is piled up in the frame. When this is filled, it is drawn to the stack. It is readily seen that this contrivance may be made of varying capacity, either small enough for use in getting in hay on a small farm, or large enough to gather a ton at once if needed.

**A HAY WEIGHING RACK.**—"L. A. W.," gives us a description of a rack for weighing hay. It is made to rest upon a platform scale, and is five feet long, two and a half feet wide, and higher at the back than at the front, as shown in figure 6. It is made of light boards, and will hold 350 lbs. or more of hay, which may be weighed at one time. In using the rack, small blocks are put under the sides, *a, a*, and when it is filled, these are knocked out so that the rack drops upon the platform of the scale. By

attaching cords to the four corners of the rack, the hay may be weighed by means of a common steel-yard of sufficient size for the purpose.

### What is Atavism?

The term Atavism, from *atavus*, an ancestor, is applied to the recurrence of any peculiarity of an ancestor in a succeeding individual, after an intermission of a number of generations. An illustration will make the above definition clear. A herd of polled hornless cattle had existed for a long time in the Kennebec Valley, but finally became extinct. Thirty years after the last hornless cow was killed, a polled animal made its appearance on the same farm as an out-crop of the old herd. Under the head of *Reversion*, Mr. Darwin gives many examples of atavic descent. Striking instances of atavism are found among pure-blood pigeons, where there is an occasional bird with the characteristics of the wild pigeon strongly developed. During the last century, certain breeds of sheep have been bred with scrupulous care, yet now and then a spotted or "black sheep" makes its appearance. The same tendency to revert to an old ancestral form is possessed by plants, and especially is this the case if there is provision made by nature for inter-crossing, and the formation of hybrids. Dr. Miles, in his "Stock Breeding," mentions a case where a woman had a sixth finger on one hand;

Fig. 5.—A HAY GATHERER.

out of eight children, only one possessed an extra finger, but both hands were affected. One of the sons had two sons, and seven daughters, all with hands as usual. One of these daughters had a son with six fingers on each hand. In this case the defect was absent for two generations, and then returned to the family, appearing in both hands instead of one.

The medical journals give cases where insanity, and other striking disorders have been traced back to some remote ancestor; the trouble, as it were, retaining its hold for a number of generations unobserved, and then came out because the subject was especially adapted for its development. Such

Fig. 6.—A HAY WEIGHING RACK.

peculiarities are dormant, or as they are usually called, *latent* characters. With this view, a living being is a wonderfully complex bundle of tendencies and counter-tendencies; swaying and balancing between the contending forces of *heredity*, or the inclination to be like the immediate parent, and *atavism*, or *reversion*, the clinging to old traits, which, if left to act alone, would sooner or later take all forms of life back to the original ancient types.

### The Villager's Pig.—How To Keep It.

A large number of our village subscribers keep a cow, and one or more pigs, just to save the waste from the table, and to help in the support of the family. Both are important sources of income when properly managed. The inevitable waste from the kitchen in an ordinary American family amounts to a good deal in the course of a year. It may as well be turned into pork, sausages, head-cheese, spare ribs, and lard, as to be thrown away. A neighbor, who has a vegetable garden, and studies thrift, has just slaughtered two pigs, weighing 598 lbs., and worth \$35.88 at the market price. The manure made from them is worth ten dollars at least. Two small pigs were put into the pen April 6th, and came out well fattened November 21st, about seven months and a half. The food consumed consisted mainly of sour, and buttermilk, kitchen waste, small potatoes, cabbage, turnips, sweet corn, wind-fall apples, and other wastes from the garden. To this was added enough Indian meal to keep them constantly full fed from spring to fall. A good pen is an important item in feeding pigs. The sleeping apartment should be dry, and be kept well littered with straw, leaves, or

Fig. 1.—A "HORSE."

meal after he is put into the pen, and should never be hungry enough to squeal. It requires some judgment in equalizing the rations, as well as in regulating their time. Much less of Indian meal is required for a ration, than of cooked potatoes, and less of potatoes than of kitchen waste. If anything is left in the feed trough, the ration has been a little too large, or not quite good enough. A pig should have all he can eat up and digest. A variety of food should also receive attention. The raw vegetables and fruits from the garden are excellent appetizers, and enables the pig to consume more meal. The meal may be mixed with cold or boiling water, with milk, or hoiled fruits and vegetables, as suits convenience. It may be varied with unground corn, buckwheat, or a mixture of ground grains. The time spent in caring for a pig usually comes at meal hours, and may be balanced by what we learn in the school of economy. There is perhaps no animal that will exhibit more satisfaction, and give greater returns for good care and feeding, than a pig; and on the other hand a hungry one without a warm home—one that has not had a proper bringing up—can make itself exceedingly disagreeable, both as to general appearance and the noise that it will produce; besides, such an animal is without profit. As a rule, it pays the villager to raise his own pork, and it pays him the greatest profit when he takes the best care of his pig. C.

### Mines and Mining Terms.

It will be remembered that in the January number the various mining terms, *bed, vein, float, winze*, etc., were explained, and we closed with the miners at work. Sometimes there is found in a vein where it is greatly enlarged, a large mass of barren rock containing no valuable mineral and of a kind different from that of the vein; this is known as a *horse*, shown in figure 1, where the vein matter is seen at each side of the enclosed mass or "horse." To meet with a horse in a large vein is a great disappointment, and it often occasions an enormous increase in the cost of working the vein. In large mines a "cage" is used, which is precisely similar in its construction and

Fig. 2.—VIEW OF SHAFT, WITH TRUCK AND ELEVATOR.

sea-weed. From one-half to two-thirds of a pig's life is to be spent in sleep, if it is well treated. Give the pig the materials, and he will make a nice bed and keep it clean. The remainder of the sty is of less importance. There should be room enough to compost the manure, liquid and solid, with garden soil, corn stalks, weeds, and other refuse matter. The pig is unrivalled as a manufacturer of compost. Its good effects will be seen in all parts of the garden, where it is spread the following season. Regularity of feeding, three

Fig. 3.—STEAM DRILL AT WORK.

times a day, is one of the secrets of success. This may be at your own meal times, if your wife is a good house-keeper and keeps a clock in the kitchen. Good digestion depends upon regular meal hours for man and beast. There is then very little temptation to over eating, no cloying, and no spells of refusing food. A pig should never lose a

upon it, which engage with the catches on the rods. These cams lift the rods and stamp heads, and then release them, when the stamps fall with great force upon chilled iron blocks under them, in a trough

Fig. 4.—STEAM DRILL—ENLARGED VIEW.

or box, crushing the ore that is thrown into the trough, into fine powder. The crushed ore, if silver, is taken to the smelting furnace, but if gold, is amalgamated with mercury, and is thus separated from the rock or any base metal which may be mixed with it. The gold is freed from the mercury and melted into bars, and the silver is cast into blocks called "bricks," fig. 6, of which great piles have been seen heaped up on the pavements in front of express offices in the mining towns. The gold and silver thus obtained is partly sent to the mints to be coined into money, and more or less is worked

Fig. 5.—PLAN OF STAMP MILL.

up into jewelry, and ornaments of various kinds, of watches, chains, spoons, forks, plate, and numerous other articles of use; some gold and silver are used in photography, and some in medicine; in fact, the uses of these "precious" metals, so-called because they do not rust or waste by oxidation, are much more numerous than is generally supposed.

### Spreading Manure from the Cart Tail.

It is pretty well settled, that barn-yard manure, or the compost heap, can be spread at any season of the year, without much waste from evaporation. There is, however, a great chance for waste of labor, in the final disposition of the manure, whether we handle it once, twice, or thrice. The old style of farmer was wont to cart out part of his manure in the fall, to put it in large heaps upon the ground that was to be

Fig. 6.—"BARS" AND "BRICKS."

broken up for corn, in the spring. After the ground was plowed, and harrowed, and the rows marked, the large heaps were distributed in small piles, by the cart, and then were dropped by the hod, or basket, in the hill. This made three handlings of the manure before the crops could use it, and added very largely to the cost of the fertilizers. Whether we use manure as a top-dressing, or for cultivated crops, it makes a large saving to handle it but once. For top-dressing grass lands, it is clear enough, that manure is most evenly, and economically, distribut-

Fig. 1—VIEW OF A CONVENIENT DUCK-HOUSE.

ed from the cart tail. So far as hoed crops are concerned, and the oats, and grass, that follow, it is probably better that the manure should be spread broadcast than that it should be dropped in the hill. The saving of the two handlings of the manure is clear gain. It is the common practice in some districts to spread fertilizers late in the summer or fall upon the sod that is to be broken up for hoed crops the next season. They claim that the manure is more equally distributed, and that by increasing the growth of grass the sod is made richer, and better crops are secured the following season. We need to carefully study the shortest and best methods of getting the fertilizers into the soil where they can do their work.

### Will it Pay to Raise Ducks?

Two years' experience with a flock of Pekin ducks has convinced the writer that there is a satisfactory profit in raising these birds. But the conditions must be favorable, and these include a water-run, either a stream or pond, in which the ducks can gather food, and a house conveniently arranged for securing the eggs. The first year a beginning was made with a trio of the birds, and these were conveniently accommodated in an ornamental rock-work house among some evergreens on a side lawn. A neighboring stream of water

Fig. 2.—GROUND PLAN OF THE HOUSE.

kept the ducks out of mischief in the day-time, and they came home regularly at night; they were not let out in the morning until the eggs had been secured. The two ducks laid 202 eggs the first season; of these, some were sold, some eaten, and the remainder set under hens. "Bad luck," in which may be included the destruction of three-fourths of the eggs when under the hens, and the killing of several of the sitters by a stroke of lightning, which went through the poultry-house, reduced the produce of young ducks to between 30 and 40. But one of these died after leaving the nests, which goes to prove the hardness of this variety. The young ducks thrived well, and when

six to eight months old weighed five to six pounds on the average. A large portion were killed and eaten; the flesh was found to be remarkably juicy and tender. The retail market price of such ducks was about 25 cents a pound, so that each would be worth at least \$1.25. The second year it was necessary to provide larger accommodations, and a house was made for them on the bank of a pond adjoining a brook in which there are abundance of water-cresses and other food, both vegetable and animal. The water-cress is eaten with avidity by ducks, and

has myriads of snails and other water animals upon it. A plan of this house is shown at figures 1 and 2. For 50 to 100 ducks it should be 30 feet long, 12 feet wide, and from 4 feet high at the front to 6 or 8 feet in the rear. Entrance doors are made in the front, which should have a few small windows. At the rear are the nests; these are boxes open at the front. Behind each nest is a small door through which the eggs may be taken. It is necessary to keep the ducks shut up in the morning until they

have laid their eggs, and a strip of wire netting will be required to enclose a narrow yard in front of the house. Twine netting should not be used, as the ducks put their heads through the meshes and twist the twine about their necks, often so effectively as to strangle themselves. To avoid all danger, the wire fence should have a 3 or 4-inch mesh. The Pekin ducks are prolific layers; a fair yearly product for a duck in its second year is 120 eggs, and 60 to 80 for a yearling. Their feathers are of the best quality, white, with a creamy shade, and 5 ducks weighing 5 pounds each, have yielded, killed in the winter-time when fully feathered, more than one pound in all. It will be right to pick the ducks when moulting is beginning; the feathers are then loose and are picked easily, and without injury. This will considerably increase the yield of feathers, and will prevent a useless loss; otherwise the loose feathers from 20 ducks will be found spread over their whole range.

### Separating Cream by Centrifugal Force.

The Swedes have long been known as most expert dairymen, and for many years past those of the craft in other countries, have been borrowing ideas and practices from them. Our old setting of milk for cream is an old Swedish practice, and the deep cans now in use, were originally Swedish, and some of our newer churns have a similar origin. A most important innovation, and, perhaps, a grand improvement in dairying, which has been recently introduced into this country, is the invention of a Swede. It is known as the "Centrifugal Creamer," and is intended to remove the cream by mechanical means—centrifugal force, in fact—to take the cream from the new milk, and thus avoid the necessity of setting the milk at all, whether in pans or in deep cans, with all the trouble, time, and cost, incident to that so far necessary and risky process. Here we give engravings of this new dairy machine, which promises to make a revolution in our dairy practice. It was first exhibited at the great English dairy fair, at Kilburn, where it obtained a silver medal, and at Haarlem the Agricultural Society awarded it a silver-gilt medal. Its inventor claims for it the following advantages. The cream can be separated from the milk as soon as it is drawn from the cow and aired; the use of ice is unnecessary; there is no setting of milk for the cream to rise; all the cream is taken from the milk, and the production of butter is consequently increased; the skimmed milk is perfectly fresh, and may be used at once for any desired purpose, with

out loss of sweetness; the quality of the butter is improved, as the cream is separated in a perfectly pure condition; the process is easy and simple; the machine is easily cleaned; lastly, the separation of cream may go on continuously so long as fresh milk is poured in and the skimmed drawn out. The operation depends upon the principle, that in a rapidly revolving vessel, the heavier contents are forced, by the action of their weight, to the outside, while the lighter gather in the center. The work

Fig. 1.—THE "CENTRIFUGAL CREAMER."

is done as follows: The receiver, which is made of steel, and is supported by a vertical axis turned by a pulley 6,000 in a minute, is filled with milk, by means of a funnel, which passes into the chamber, through the central column, *a*, fig 2. The rapid rotary action immediately begins to separate the heavy milk from the light cream, and in a short time the outer layers of milk are completely separated. As the fresh milk is poured in, this separated milk is forced by it into the tube, *b*, and arrives through it into the chamber, *B*, from which it escapes by a pipe. The cream in the center being continually augmented by the process of separation is raised by the entering milk into the tube, *c*, and passing by the tube, *f*, into the chamber, *C*, escapes by another pipe into proper receptacles; thus the process continues, so long as any milk is introduced. It should follow that as water is heavier than the cream, if a quantity of it should be introduced when the milk is all in, the cream remaining may be separated to the last drop, until the milk, too, is

Fig. 2.—"CREAMER" SEEN IN SECTION.

exhausted, when a stream of water passed through for a time, would cleanse the machine perfectly.

This conclusion, however, is our own, and we do not know that it is so claimed by the inventor, but it is a poor principle that will not work on its own theory as well with one liquid as with another. If the machine will separate one composite liquid into its heavier and lighter parts, it should certainly separate another, and this machine should be expected to remove cream from water as well as from milk.

### Making a Jumper.

A "Jumper" is a light, one-horse sleigh, made to carry passengers, or a light load. It may be made of hickory or oak poles, dressed into shape, and a few bolts; or the joints may be mortised into tenons in the usual manner. A rustic jumper made of timber with the bark on, is a very appropriate rural conveyance, and would answer many common purposes. To make a neat and strong one, proceed as follows: Choose two hickory poles 4 inches thick, and dress them sufficiently, steam the smaller ends, by wrapping bagging around them, and soaking them in boiling water. When they are flexible, bend them into the desired shape, and fasten them with cords until they are set, and will retain the bend. These are the runners. The posts are mortised into these runners, and into the benches in the usual manner, and the slides are connected by cross-benches bolted with carriage bolts, or mortised, and are braced sufficiently to make the frame stiff. The floor is laid upon the benches, and the body and seat are built upon it. The front

A RUSTIC JUMPER.

is closed in with basswood, or other boards, steeped in hot water, until made to bend into the proper shape. The shafts are fitted to eyes put through the front part of the runners in the ordinary way. The runners should be shaved off smoothly on the bottom, to make them slip easily.

### Barn and Barn-Yard Rakes and Brooms.

In cleaning barns and barn-yards, very stout rakes and brooms are needed. Some farmers, and even dairymen, never think it necessary to do more towards cleaning their barns than to fork out the litter, leaving the floors still covered with small particles of filth. It is now considered by the best dairymen, and very rightly so too, that perfect cleanliness in barns is absolutely necessary to the production of pure, clean milk and good butter; and cleanliness certainly includes clean floors. To preserve this cleanliness, every barn should be provided with a strong rake and a stiff broom. A rake which will be found useful, and that can be made at home, is shown at figure 1. It is made of a head block in which some curved teeth are inserted, and to which a convenient handle is fitted. This will be found to gather the manure better than one with straight teeth. A broom may be made of birch twigs placed between flat pieces of board, as

Fig. 1.—BARN-YARD RAKE.

shown at figure 2; the pieces being bound together firmly with twine, or preferably, with wire. A handle is fitted in such a position as to easily push

the broom in sweeping; it may also be drawn forward like a rake. A useful broom is made of rattan, which is very durable for farm use, and can be obtained at most well stocked implement stores.

### The Precocity of the Jerseys.

Col. David Taggart, of Northumberland, Pa., President of the Penn. Agricultural Society, at that Society's remarkably successful exhibition last fall made some statements of his experience with Jersey cattle. At the request of several of our readers who heard him, he has written out the essential

Fig. 2.—A BIRCH TWIG BROOM.

points of his remarks for publication in the *American Agriculturist*. Colonel Taggart writes:

Twenty-eight years ago, in company with three other aspiring farmers' boys, I visited the great "York State" Fair at Rochester. Here we found nearly two hundred magnificent Shorthorns, scores of fine Devons and Herefords, and four little Jerseys. I said to one of my fellows, that "if I was ever fixed for keeping a herd, that the Jerseys were my sort."—I have owned one or more Jerseys for the last sixteen years, but only since 1873 could I give them my personal attention. I have now nine cows in my little herd, and I propose to give you their achievements in calf-dropping. I reared all but the oldest two. "Ruby," dropped March 2, 1872, had her first calf June 3, 1873; her second, May 15, 1874; third, March 29, 1875; fourth, (Bessie), Feb. 1, 1876; fifth, January 2, 1877; sixth, (Mary), Nov. 12, 1877; seventh, Oct. 5, 1878; eighth, Aug. 27, 1879. Whereas, you will perceive, she was not quite 7½ years old. At the same rate when she has had a calf and a half more, she will have gained a whole year. She is a large, full-barrelled, and hardy cow, in spite of her early and rapid breeding.

"Nelly," dropped April 7, 1873; calved June 10, 1874; July 27, 1875; July 9, 1876 (Annie); June 27, 1877; April 27, 1878; March 31, 1879; or six calves before she was 6 years old. "Bessie," Feb. 1, 1876; 1st calf (Sally) July 8, 1877; 2d, May 7, 1878; 3d, March 4, 1879. Three heifer calves in 19 months and 26 days—and she only 3 years, 1 month, and 3

Fig. 3.—THE BROOM FINISHED.

days old. "Annie," July 9, 1876; 1st calf (Susie), Dec. 25, 1877; 2d, Oct. 25, 1878; 3d, Oct. 8, 1879. Three heifer calves again. "Fanny," July 2, 1876; calved March 28, 1878, and May 20, 1879. This animal, bred in-and-in, having three-fourths of the blood of her sire, has not done so well. "Jennie," January 18, 1877, aborted at about 7 months, Sept. 23, 1878; 2d calf, Aug. 8, 1879. She is now as well developed in barrel and bag as a four-year-old. "Sally," July 8, 1877; calved Feb. 16, 1879. This made "Bessie" a grandmother at 3 years and 15 days. "Mary," Nov. 12, 1877; calved May 11, 1879. "Susie," Dec. 25, 1877; calved May 22, 1879—one month and 18 days before "Annie," her mother, was three years old. "Hannah," out of imported "Antic," sold to the Hon. John B. Packer, was only 14 months and 20 days old when she

dropped "Fanny," and her half sister, "Lillie," was a mother at 14 months, 23 days. To recapitulate:

Nelly	was a mother at	14 months and	3 days.
Hannah	"	14	" 20 "
Lillie	"	14	" 23 "
Ruby	"	15	" 1 "
Susie	"	16	" 27 "
Bessie	"	17	" 7 "
Annie	"	17	" 16 "
Mary	"	17	" 29 "
Sally	"	19	" 8 "
Fanny	"	20	" 26 "

Jennie had had a calf and seven-ninths when 2 years, 6 months, and 20 days old. None of these young animals raised by myself have thus far gone dry. They freshen up from 2 to 4 weeks before calving, and attain almost their full quantity. If any one asserts that this early breeding is hurtful, let him come and see for himself. Mr. Packer thought "Hannah" was too big, and if any one has a finer 3-year-old than "Bessie" and "Annie," or a bigger 2½-yearling than "Jennie," or more thrifty milking calves than "Mary" and "Susie," I will go far to see them. It is logical to believe that the sooner a cow or other animal can acquire a good habit, the better it will be for them. And surely it is a good habit for cows to drop valuable calves and give milk. If I can render mine, not merely self-supporting, but profitable, at 15 or 18 months, by keeping the right breed and feeding liberally, I am more fortunate than he who produces the same result in 30 or 36 months, by half-feeding. The half-feeding for the longer period will cost much more, both in money and labor, than the full feeding for the shorter time, and produce animals of less sym-

Fig. 1.—THE RING AND STRAP.

metry and vigor. As a rule, the finest physical specimens of dogs, hogs, cattle, horses, jackasses, and men, and not stunted in their development, are those that have never felt the pinchings of poverty.

### Ring and Swivel Cattle Fastening.

Mr. D. S. Depue, Ionia, Mich., sends a method of fastening cattle, of his own devising, which he has used for a long time, and finds very satisfactory, preferring it to any other. The fastening consists of an iron ring, four inches in diameter, and about an inch in width, which slides readily upon an upright post. A swivel-ring turns in the large ring, being fastened to it by a swivel-point passing through a hole in one side of the large one, and headed down over a washer in the usual way. The small ring carries the strap, which, for strength and comfort, should be rather wide and of sufficient length to buckle around the animal's neck, and no more. In order to keep the strap in place, a piece of wire may be placed around the fold of the strap, near the ring, as shown in figure 1. When the fastening is not in use, it can be pushed up to the top of the post, and the strap passed over a peg in the timber overhead, as shown in figure 2.—"The swivel is the climax of all." Mr. D. is satisfied that his cattle, thus fastened, are comfortable, and safe, and the method is easy of application.

Fig. 2.—STRAP FASTENED UP.

### Cattle Shelters on the Prairies

In the far western grazing regions, where natural protection of ravines, groves of timber, etc., is not

Fig. 2.—CATTLE SHELTER FOR THE PRAIRIE.

available, shelters of the kind shown in the annexed illustrations are provided. Poles are set in the ground in rows about 16 feet apart, and 12 feet in the rows. Cross-beams or poles are spiked to these to hold a frame of lighter poles, and others, placed sloping, are laid upon the north side as shown at figure 2. Piles of hay are heaped over these frames, as seen at figure 1, and these furnish at the same time, shelter from storms, and feed for the protected animals. A large number of these shelters are often made on the range, and some of them are hundreds of feet in length, and so curved as to protect from north-west and east winds. Af-

The smoke house may be of any shape, but it should be provided with cleats fixed to the sides, upon which the hanging-bars rest. A pulley is fitted inside to the top of the building, and a hoisting rope is passed over it. The hanging-bar is hooked to the rope and two spreading ties, as shown, so that it will not tip easily when it is loaded. The hams or bacon are hung upon hooks fixed in the hanging-bar, and the whole is hoisted up to the cleats, when the bar is swung around so that the ends rest upon the cleats; the rope is then released from the bar by means of a small rod, and another bar may be loaded and raised in the same way, and so on until the meat is all suspended.

### Top-Dressing in Winter.

The practice of top-dressing grass land during the fall and winter months, is slowly increasing. The common apprehension, that much of the manure is wasted by running off while the ground is frozen, is giving place to better views. There never was much basis for this opinion. The same soft weather or rain that makes surface water, opens the soil to receive all that leaches away from the manure. The surface soil of dark mould, six inches or more in depth, has an easy task to take care of a heavy dressing of stable manure. If fifty loads were to be spread evenly over an acre, it would make less than a half inch in depth. The grass stubble, even upon

a gentle slope, would hold the manure in place, in all ordinary rains and snows. Experiments show conclusively, that the fertilizing properties of the manure remain where it is spread. The change which our railroads and steamers have made in Eastern agriculture, is turning the attention of farmers more and more to top-dressing, as a means of keeping up the fertility of their meadows without plowing, and re-stocking the land. There is so much competition from the new states in grain and meats, that the eastern farmers can only raise them at a very small profit, or even loss. Grass pays better than almost any other crop. This he can turn into butter and milk for the village market, or into hay, which is too bulky to admit of transportation from the prairie states. The old rotation of corn two years, oats one year, and grass three years, hardly pays in the Eastern States. Labor is expensive, and it costs to plow, cultivate, and re-stock land. Grass and hay are paying crops, and if the meadows can be kept up to the production of two or three tons to the acre, by top-dressing with barn-yard manure, it is improved husbandry to adopt the change. It is demonstrated in a multitude of cases, that this can be done. We visited, recently, a farm on which were meadows, that had not been plowed since they were first cleared from the forest, some two hundred years ago. They were not far from the barn-yard, and produced the best hay upon the farm. Any falling off in the production, indicated the need of more top-dressing, which was faithfully applied. The season favors this mode of fertilizing, and there is economy in handling the manure but once. The teams are in their best condition during the fall and winter, the weather is cool, and much power is saved by drawing the loaded carts over the solid

earth, or the sleds on the snow. Much labor is saved by spreading the manure from the cart tail, while drawing it upon the meadows. The great pressure which comes upon the farm hands and the teams in April and May, is forestalled by this winter work. About the best place for manure, as it comes from the stable or the compost heap, is the surface of the meadow. CONNECTICUT.

### A Dumping Sled.

A sled for drawing manure, stone, or other coarse materials, from which the contents can be instantly

Fig. 1.—A DUMPING SLED.

dumped, such as is shown in the engravings, will often be found a very convenient farm vehicle. It consists of stout runners, upon which the plank deck is fastened, and a pair of inverted runners are fastened to the upper side (fig. 1.) These operate as side planks and runners at the same time. The sled is drawn by a stout chain and ring fixed to the front. A longer chain is fastened to the back of the sled, as shown in the engraving. The draft-chain is fastened to a snap-hook, which may be released by pulling the cord, as shown at figure 2. Then the dumping-chain comes into use, and tips the sled over, releasing the load. The ring is then attached

Fig. 2.—THE DUMPER LOADED.

to the draft-hook; the dumping chain, fixed as before, and the sled is ready for re-loading; this time upon the reversed side. It is in fact two sleds in one, and by rounding the runners, front and rear, it may be drawn equally well from either end.

### How to Make a Snow Shovel.

Every house should be provided with a snow shovel, ready for use at times that always come unexpectedly. A broad wooden shovel will be of more

Fig. 3.—THE CHAIN FASTENING.

use in moving snow from paths and roads than a steel one, and it may be made very easily, as shown in the illustration. A broad piece of thin board is chosen, and a cross-cleat and braces are nailed to it. The handle is fitted, and the edge of the shovel is

A HANDY SNOW SHOVEL.

protected by a piece of sheet-iron or tin nailed over it. If the board is likely to split, a light cleat may be fastened across it on the underside with wrought nails, clinched to make them hold firmly. The engraving hardly requires explanation. There

are but few farms upon which a snow plow will not pay for the trouble of making it at the first heavy fall of snow—to say nothing of the fun it affords the youngsters. After all the work of the plow is done, the "finishing touches" require the snow shovel.

### A Smoke-House Convenience.

A method of hanging the meat in a smoke house

A SMOKE-HOUSE CONVENIENCE.

without the necessity for reaching up, or using a ladder, is shown in the accompanying engraving.

**Double White-Flowered Horse Chestnut.**

BY W. C. BARRY, MT. HOPE NURSERIES, ROCHESTER, N. Y.

Although the Double-flowered Horse Chestnut was introduced to this country in 1852, this superb variety has not acquired that popularity which its merits warrant. It is surprising that so important an addition to our hardy flowering trees should not have met with greater favor, and I can only account for this lack of appreciation by the fact that its many good qualities have not been understood. It was figured and described the first time in America, in the "Genesee Farmer" for 1852. Since that

writes. "The freedom of this excellent fruit from insect depredations, is almost as much a marvel, as its great hardiness. Usually the fruits which "the worms" pass by, are not of a high grade, the Damsion plum for example. But here is a fruit which yields to none of its compeers; and the concurrent testimony is, that year after year, it remains unurt by insects, as well as by cold. An explanation of this is ventured with some diffidence. Most of the insect pests prefer seclusion for their work. Fruits borne in clusters, and touching each other afford them privacy. Rawle's Janet is a familiar example. This good apple sets its fruit in clusters of two,

though it makes but little shade, owing to the fineness of the foliage. As the peculiar form of the leaves distinguishes it from nearly all other native trees, and especially from the Common Locust, we give in the engraving a small twig with several leaves. These are what botanists term *twice-pinnate*; simply *pinnate* leaves are very common. The Sumachs, the Ailanthus, the Common Locust, and many others, affording examples. In the pinnate leaf, there is a leaf-stalk, or common petiole, along the sides of which are arranged pairs of small leaves, or *leaflets*, with or without a terminal odd one. In the twice-pinnate (*bipinnate*) leaf, the leaf-

THE DOUBLE WHITE-FLOWERED HORSE CHESTNUT.

time it has been propagated and disseminated in but limited numbers, and, as yet, fine specimen trees are seldom seen. The first imported tree, obtained from the late Mr. Rivers, is now growing on the grounds of Ellwanger & Barry, at Rochester, and is about 60 feet high, its branches covering a circle 20 feet in diameter. It is as hardy as the common Horse Chestnut, of vigorous, erect growth, regular pyramidal outline, with rich, dense foliage and splendid inflorescence. Few trees can lay claim to a greater combination of attractive features, and it possesses several characteristics which render it even more desirable for ornamental planting than the ordinary form. In habit it is more upright and formal, its height being about three times its breadth, and a fully developed specimen is a perfect pyramid of verdure. Its flowers, as seen in the engraving, which is one-fifth the real size, are perfectly double, and in spikes larger than those of the single flowering kind, resembling gigantic hyacinth bouquets. They appear in remarkable profusion at the season of bloom, which is about two weeks later than that of the common kind. On the lawn this tree forms a conspicuous and pleasing object, and although I have never seen it used as a street tree, I think it admirably adapted to the purpose. It produces no fruit, a characteristic which many will regard as an important point in its favor, as much litter is avoided. A proper consideration of the merits of this fine tree will induce amateurs and planters to employ it oftener in the ornamentation of public and private grounds.

**Dyehouse Cherry.**—As we first brought this fruit to notice, it is gratifying to hear good accounts of it from all quarters. "R. J. B.," Fairfield Co., O.,

three, and four, and it is found profitable to thin it to one on a spur, not only for the increased size of the remaining apples, but to get rid of the insect injuries which otherwise render the crop of but little value. Now, with the Dyehouse, the leaves are but moderately plentiful, and the fruits stand out, each by itself, often in full sunshine, so that the green of the leaves is obscured by the brilliant red of the ripe cherries; and the little marauder, falling to find a quiet nook, takes his leave."

**The Honey Locust as a Hedge Plant.**

In localities where it will endure the winter unharmed, there is probably no plant so serviceable for hedges as the Osage Orange. But besides a northern area in which we know that this is not hardy, there is a broad belt in which its hardiness is doubtful, it varying with local influences. From both these districts, and especially that of the uncertain hardiness of the Osage Orange, there come frequent inquiries for some hedge plant which shall be as serviceable as that, and perfectly hardy. We know of no other so well meeting these conditions as the Honey Locust. Before considering its value as a hedge plant, it will be well to describe the Honey Locust, as we have found that it is very frequently confounded with the Common Locust; the fact that this is often called the "Sweet Locust" greatly aids in confounding the two. The Honey Locust is a native of the Middle, Western, and South-western States, it being more common west than east of the Alleghenies. Along the banks of the rivers it often reaches 80 and 100 feet in height, with a trunk three and four feet in diameter. The broad head is remarkable for its lightness and grace,

lets themselves are compound, the common, or main leaf-stalk, instead of leaflets, has smaller leaf stalks, which themselves bear leaflets. A reference to the engraving will show this. This difference in the foliage will usually allow the Common Locust and the Honey Locust to be distinguished at once; in the one case the leaves are simply pinnate, and in the other doubly, or twice-pinnate; though it sometimes happens that the Honey Locust bears some once-pinnate leaves, this is not the rule. The difference in the flowers is equally striking; the Locust proper has long hanging clusters of large, white, pea-shaped flowers, which are noticeable for their fragrance, and are very showy. The Honey Locust, on the other hand, has flowers so small and inconspicuous that only those who observe closely ever notice them at all. They have not the pea-shape of the flowers in most of the family (*Leguminosae*) but are regular, in small spikes; which, being greenish, are likely to escape notice. The flowers are of the kind called *polygamous*, i.e., there are staminate, pistillate, and perfect flowers, either in the same tree, or on different trees. On trees where the flowers are all staminate, as in figure 1 in the engraving, there will, of course, be no fruit. Nor will there be on trees with all pistillate flowers like 2, unless there are other trees with stamens near by to fertilize them; while trees with the perfect flowers (3 in the engraving) will produce fruit. In this tree the fruit is a much flattened pod, an inch, or more, wide, and 10 to 20 inches long. These are often curved and twisted, and very conspicuous upon the tree; Dr. Gray once aptly described the appearance of the tree in fruit by likening it to a tree hung with apple parings! The intervals in the pod between the seeds are filled with a sweet pulp, on account

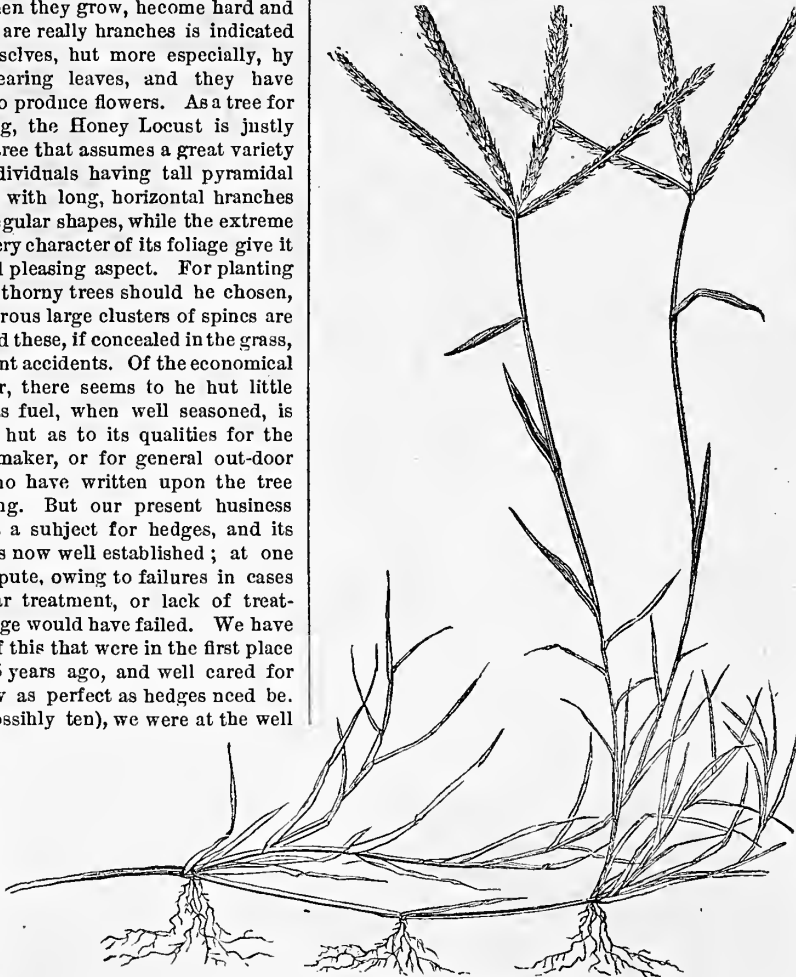

THE HONEY LOCUST (*Gleditsia triacanthos*).

of which the pods are eaten by many animals; boys try to "make believe" that it is good, but they soon tire of its mawkishness. An infusion of the pulp has sometimes been used for making a domestic beer. But the most noticeable feature of the tree, and the one in which its hedging value resides, is its thorns. The thorn often being triple, i. e., a main thorn with two branches, has given the tree one of its common names—"Three-Thorned Acacia," its foliage having a close resemblance to that of the Acacias; but there is no regularity in the shape of the thorns, they being found in great variety, from a mere simple point to very much branched and complicated masses, armed in every direction. Different trees vary greatly in their armament, some being quite thornless, while others, according to Bryant, "hurtle with thorns to such a degree, that not even a squirrel can ascend them." These thorns are really branches developed as spines; the tree produces, besides buds at the axils of the leaves, supernumerary buds at some distance above the axil; these, when they grow, become hard and pointed; that they are really branches is indicated by branching themselves, but more especially, by their sometimes bearing leaves, and they have even been known to produce flowers. As a tree for ornamental planting, the Honey Locust is justly esteemed; it is a tree that assumes a great variety of forms, some individuals having tall pyramidal heads, while others with long, horizontal branches assume flat and irregular shapes, while the extreme lightness and feathery character of its foliage give it a most graceful and pleasing aspect. For planting in grounds the less thorny trees should be chosen, as those with numerous large clusters of spines are apt to drop them, and these, if concealed in the grass, may cause unpleasant accidents. Of the economical value of the timber, there seems to be but little known; its value as fuel, when well seasoned, is generally admitted, but as to its qualities for the builder or cabinet maker, or for general out-door farm uses, those who have written upon the tree say little or nothing. But our present business with the tree is as a subject for hedges, and its value for this use is now well established; at one time it was in disrepute, owing to failures in cases where, under similar treatment, or lack of treatment, any other hedge would have failed. We have examined hedges of this that were in the first place properly planted 25 years ago, and well cared for since, that are now as perfect as hedges need be. Some years ago (possibly ten), we were at the well known nursery of Ellwanger & Barry; they had recently finished planting a long line of Honey Locust hedge upon their grounds. Having seen, as it were, the very beginning of this hedge, we have watched its progress with interest in subsequent visits to Rochester; not having time when there last summer to visit the hedge (at some distance from the attractive portion of the grounds), we have since written to learn its present condition, and the esteem in which it is held after an experience of several years. After giving answer to some questions in detail (which we shall use at another time), Mr. Barry writes: "Some neighboring farmers here have fine Honey Locust hedges on their farms, and they have never received more than ordinary care. For our climate it is the best hedge plant that I know of." After this nothing more need be said in regard to its excellence. Having given so much space to describing the plant, the method of making a hedge must be left for another month. We may here say, to answer a number of inquiries, that the plant is always raised from seeds planted in spring; these may be had of the leading seedsmen, the catalogue price being 60 cents a pound. Young trees are offered by several nurserymen, the usual price being \$8 to \$10 the thousand, according to size. We mention these points to save a large number the trouble of writing for the information.

### About Bermuda-Grass.

Bermuda-Grass, or Scotch-Grass in our Southern States, Creeping Dog's-tooth-Grass in England, Chiendent in France, and Doob or Durra in the East Indies, are different common names for the grass called by botanists *Cynodon Dactylon*. In one respect it is the most remarkable grass within our knowledge, as one can with equal ease find that it is the most valuable of all grasses, and one that is to restore worn-out Southern fields, and bring untold blessings wherever introduced, or that on the other hand that it is a curse to the soil, and that when this once gets a footing upon a farm, the owner may as well give it up at once, as to do so at the end of a struggle in which he is sure to be worsted. With such widely differing views, it is likely that there is some truth on both sides; but it is not to our purpose at present to discuss the value of Bermuda so much as to describe the grass itself and its methods of propagation, in order to

BERMUDA GRASS (*Cynodon Dactylon*).

reply to many inquirers, who wish to make a trial of it. No doubt these have come to the conclusion that if half that has been said in its favor is true, they will run the risk of all the alleged bad qualities that have been ascribed to it. Bermuda-Grass has slender creeping stems which run along upon the ground, throwing clusters of roots into the soil at every joint, frequently branching, to form a net-work of such stems from which arise annually the erect and leaf-bearing stems. These prostrate stems run to a great distance; one writer states that they will pass over a rock six feet across, and soon hide it from view. The upright stems vary greatly with the quality of the soil; sometimes they are but a few inches high, forming a dense mat, and again growing tall enough to make two tons of hay to the acre at one cutting. The difference of appearance in the grass as it grows on dry and sandy soil, and in a moist and rich one, is so great that some botanists have thought that they might be well marked varieties if not distinct species. The flowers are borne upon slender spikes one to two inches long, three to five of which are attached at the top of the stem, from which they

spread like rays, as in the engraving, taken from a small specimen. The structure of the spikelets, or the flowers themselves, we need not describe, as it can only be done by the use of terms familiar to only those who have made a special study of the grasses. While the Bermuda-Grass flowers freely, it has not, so far as we are aware, produced seed in this country. In reply to many who have inquired where seed could be procured, we have had occasion to state a number of times, that no seed was produced; this has called out letters from several who thought we were in error, and upon our requesting the writers to send us specimens, they have in nearly every case sent the seed of the Crag-Grass (*Panicum sanguinale*). That is, an annual, readily told from Bermuda-Grass by botanical characters, and can be known to the general observer by its much longer spikes which are usually in greater number (4 to 15) than in Bermuda. The few who did not send Crag-Grass seed, mistook the flowers of Bermuda for its seeds. But does it never bear seeds? Undoubtedly it is fruitful in some countries, indeed, Sinclair in the account of his experiments made for the Duke of Bedford and published in 1816, says: "The seeds of this highly celebrated grass in India, were communicated to the Duke of Bedford, from the East Indies, by the Marquess of Hastings." It is further stated, that the plants from these seeds produced seeds. This grass is found in all hot countries, but is thought to have been introduced here and into Australia, which could hardly have happened, save by the aid of seeds. Its wide dispersion with us, being found in Pennsylvania, and every State south of it, makes it probable that it has at times seeded, but in the hundreds of specimens we have examined, no seed, or even an imperfect one, has been found. In view of the inquiries we have had, we should think that some of our seedsmen would find it worth while to import seed from abroad. The only method by which it can now be propagated, is by cuttings. The sod is taken up and thoroughly washed; it is then run through a cutting machine, and cut fine; the cuttings (or rather choppings), are sown broad-cast, and a shallow furrow turned over them as in plowing in wheat. This method is suggested by Mr. Howard, in his useful treatise on "Grasses for the South;" we regret that he does not state what quantity of cuttings of this kind is needed for an acre. It would be well for some seedsmen, where the grass is abundant, to advertise the fact that he can supply it in sods or cuttings. The grass increases very rapidly, and if those who wish to introduce it, can get by mail a small bunch of roots from some friend who lives where it grows, they can, by growing this carefully one year, get enough to set a wide area the following spring. The value of the Bermuda as a pasture grass, is more obvious than as a meadow grass. Yet when our late friend, Mr. Affleck, of Texas, states that his regular crop was five tons of hay to the acre, and one so favorably known as Doct. Ravenel, of S. Carolina, states that by the use of fertilizers, he harvested in four cuttings, from one-eighth of an acre, at the rate of ten tons to the acre, we should think that the Southern States by growing this grass would be exporters of hay.

### The Apple Leaf Fungus.

BY PROF. WM. A. BUCKOUT, PENN. STATE AGR. COLLEGE.

Professor Buckhout sends us some sketches of the Apple Leaf Fungus upon the fruit, with the following interesting notes: "In your article on the Apple Leaf Fungus in the November number, I find no mention of the fact that besides attacking the leaves, and thereby injuring the fruit-producing power of the tree, it attacks the fruit itself, as is known to be the case in certain wild species—the Hawthorn, for instance. An excellent example of this has recently come under my notice, and, as I am not aware that such a case has been recorded in print, I send you the details. Mr. Washington Campbell, of Linden Hall (Centre Co., Pa.), brought me the leaves and fruit of the apple locally known as the 'Pound' (Fallawater of Downing), upon both of which the 'cluster-cups' were thickly scattered. Those upon the fruit were in patches about the size of a small coin, and most frequently found

about the eye. Sometimes, however, they were upon the side, and unconnected with either the eye or stem extremity. Figure 1 gives the appearance

Fig. 1.—APPLE AFFECTED BY FUNGUS.

of one of the apples, and in figure 2 is shown the effect which was produced upon the interior of another. The flesh of the apple was somewhat discolored in places, and rather hard and knotty in lines running to the core. The fruit was thus un-

Fig. 2.—SECTION OF APPLE.

Fig. 3.

fitted for use, and when attacked became stunted and one-sided in its growth. Mr. Campbell's apple crop was very materially diminished by this means. Many of the 'cluster-cups' upon the fruit were longer and larger than those upon the leaves. This was very distinct to the unaided eye. In figure 3 I have sketched several of them enlarged. They are long, curving, and horn-like. Their recurved borders often fail to separate into the characteristic thread-like parts which are so distinct a mark of the shorter cups. A second point of great interest to fruit-growers is the connection of the 'cedar-apples' with these 'cluster-cups'—a point to which you refer by an example. I am glad to be able to add another, which is so conclusive that in my own mind there is no longer any doubt of the specific identity of the two forms which are apparently so different in their nature. The trees from which the specimens were taken were rather closely set, young and thrifty. Two red cedars were growing very near them. One was small, and upon it were found a half-dozen of 'cedar apples'; the other was a moderate sized tree, upon which were very many. Upon the apple trees nearest the cedars scarcely an apple or a leaf escaped infection. A few rods off was an older orchard, separated by a narrow roadway: only an occasional apple upon these trees showed the fungus. It appears as if the Pound apple was more susceptible to attack than other kinds; for one or two of other varieties, and apparently equally exposed, showed less of infested fruit. The case seems to be worthy of being placed on record, and to offer practical proof of the relationship of the two very unlike fungi—a point upon which botanists have long disagreed."

### Rapid Tree Planting in Kansas.

[Professor Sargent, Director of the Arboretum at Harvard University, favors us with an extract from a letter written by Mr. Robert Douglas, the noted forest-tree grower, of Waukegan, Illinois. Mr. Douglas has recently completed a plantation of trees of the new hardy Catalpa (*Catalpa speciosa*), for one of the railroads of Eastern Kansas, and his method of planting, the result of years of practice and experience, will be of service to other prairie

tree-planters, or indeed to any one elsewhere planting seedling forest trees on a large scale.—Ed.]

"I wish you could have seen those raw men after we had worked them a few days. They boasted about planting 300 trees per man when they worked there last spring. When I told them that, after two days, I would make them average 1,500 trees per man, you should have seen the look they gave me. But they did it the second day, and kept it up to the end. The trees were as well planted as they possibly could be, the roots being carefully spread out by the fingers, and every tree planted firmly. Every one of those 18 or 24 men, averaging 10 hours per day, planted two and a half trees for every minute of that time! As this mode of planting is my own, arrived at after some study and experience, and reduced to the very fewest motions that can be used in planting a tree, or, rather, a plantation of trees, I trust that a description of the operation may be of interest. We call this the 'three-motion system' of planting. The land is marked off 4 by 4 feet, with a corn marker. The men are in 'gangs' of three each, two with spades and the other with 100 trees tied up neatly in a parcel with a willow. The spaders stand facing each other, taking each a row, the tree holder standing between them. The spader makes a downward stroke with the back of the spade facing outwards, and then takes out a spadeful of earth. This leaves a straight side on the back of the hole, against which No. 3 places the tree; the digger then replaces the spadeful of earth, having made just 3 motions of the spade. The tree holder takes a tree from his bundle, and with a quick motion, which is hard to describe, but easy to learn, places the tree in the hole in such a manner as to spread out the roots perfectly. In this way he tends two men, putting in the trees just as the spader raises the earth. As the spader steps forward to the next check made by the marker, he brings down the heel of his left foot close to the just planted tree, and this leaves it firmly tightened in the soil, and ready to grow."

### Twin Apples.

In a "Basket Item" given last month on page 7, we mentioned the receipt of twin Lady apples from Mr. W. W. Young, of Ky. Thinking afterwards that the occurrence of such a union of apples was of sufficient interest to put on record with an engraving, we gave one of the specimens to an artist for the picture to be made. Singularly enough, when we opened the next parcel of our English

A TWIN APPLE.

papers, there in the "Journal of Horticulture" was, to all intents and purposes, our twin apple. The account of this English twin is of special interest, as it informs us that the tree which bore it has a regular habit of producing twins, and that it has been propagated. The apple is not, like ours, of a known variety, but is probably a chance seedling. Mr. Young stated, in sending the twin Lady apple, that he found a number of twins every year. We would suggest that he examine the coming season to ascertain if they do not all come from the same tree. Of course this growing together of apples is only of scientific interest; to the orchardist, other than a few specimens as curiosities, the habit of doubling the apples (instead of the crop) would be a disadvantage. It is useful for him to know that the peculiarity may be propagated, in order that such trees may be avoided in cutting cions.

## THE HOUSEHOLD.

For other Household Items see "Basket" pages.

### Household Decorative Art.\*

BY M. G. E.

The design for a Bracket in fret-work, here given in fig. 1, is to be worked up with a chisel and vein-

Fig. 1.—DESIGN FOR BRACKET.

ing tool. The shelf, shown in figure 2, is supported by a piece of carved wood, precisely like one-half of the lower part of the back, to which it must be firmly attached by means of small screws let in from behind. The wood should be 3/4-inch oak or walnut. In drawing outlines for carving, chalk is better than pencil, as it is more readily erased, unless the pattern is delicate, as for fret-work, when a pencil line will be more easily followed. If the ornament is to be in high relief, draw the pattern boldly on the upper surface, and mark off by a line on the sides, the distance to which the first flower or leaf of the group is to be cut down. For straight lines, use the chisel, holding it upon the line, firmly in the left hand, and strike it a light blow with the mallet in the right; do not cut too deeply at once. A heavy blow is likely to break the fibre, and the piece that was intended to be left in relief will be weakened, and probably break off with a little handling. For curved lines use the gouges; if you have several sizes, one will be found to fit each curve; be careful to cut straight down, and do not let the tool slope; work slowly and carefully until the whole design is outlined. Then, with your chisels, clean away the back-ground, leaving the ornament in as high relief as desired; now sketch in the remaining leaves, treating them in the same way, clean out carefully underneath, and the work is now blocked out. Much patient labor is next wanted to perfect what is now but just begun. The veining of the leaves, the curving of the flowers, the rounding of the stems, and all the delicate tracery required must be accomplished by

Fig. 2.—THE SHELF.

the aid of the small chisel, gouges, veining, and parting tools. Cut cleanly and with thought; avoid the use of sand-paper if possible, design

\* This was prepared and intended to follow an article given in June last, but was crowded out for the time.

carefully, and execute patiently, and as the work develops, you will very soon be proud of the result.

Figure 3 illustrates a hanging hook-case, in the old English style, which must be strongly put together to bear the weight of books. While endeavoring to secure the ornamental, the useful should not be lost sight of. To the educated eye, there is nothing more distressing than the flimsy articles of furniture, with which some houses are filled, glittering with gilt or varnish, too delicate for use, and possessed of no artistic value to make their uselessness pardonable. Work need not be clumsy to be strong, and an elegance of appearance is only gained by just proportion and neatness of

Fig. 3.—A HANGING BOOK-CASE.

finish. For making these shelves, oak will be perhaps handsomest, if not less than half inch. If a turner is convenient, the twisted shafts can be furnished at trifling expense, but as some are not so situated as to be able to call upon one, I will give the simplest directions for producing the same effect. From a square stick cut off the corners from that part which is to be twisted, and plane smoothly, so as to bring to an octagonal shape, repeat this until it is sixteen-sided, this, when the sharp edges are smoothed down a little, will be nearly enough round for the purpose. Now take two strips of paper, each of half the diameter of the wood, that is, supposing the latter to be two inches thick, each strip of paper should be one inch wide. Twist them spirally round the wood, side by side, and secure them at every turn by using pins. Having done this, paste one of them securely to the wood, then remove the other altogether. The wood left exposed must be cut away with a gong to a depth of one-half in the center, and one-quarter its width at the outsides. Then smooth down and round off with the chisel; last of all using the sand-paper.

### Protection for Windows.

"When the wintry winds do blow," and with a piercing whistle rush through the windows at the sides where the sashes slide, they chiefly penetrate at the upper part of the sides of the lower sashes, where

1.—THE RUBBER CUT. 2.—THE RUBBER IN PLACE.

they almost invariably fit so loosely as to rattle continuously. To prevent both the rattling and the entrance of the cold wind, the writer hit upon the following method: Some sheet rubber was cut

into the shape shown at figure 1. These pieces fit upon the upper corners of the lower sash, the sash cord passing through the half-round hole, and the sash strip passing through the square hole at the corner. The piece of rubber is tacked upon the corner of the sash, as shown in figure 2, and should be made to fit closely to the side of the frame to keep out the wind.

### Household Notes and Queries.

**TAKING COLD.**—One of the many ways of taking cold, is by not keeping the mouth shut when out in the sharp, cold air. The tender membranes of the throat are exposed to the chilling air, and congestion ensues, in other words, the person takes cold. The cold air should be taken in through the nostrils. Man, like the lower animals, should breathe through his nose.

**DANGEROUS LIQUIDS.**—*Ammonia*, especially the stronger kinds, is dangerous, a few drops being enough to injure a person. When used for cleansing purposes it should be handled with great care, that the gas, which is given off freely in a warm room, be not breathed in large quantities, and do injury to the delicate lining of the nose and mouth. *Benzine* is a liquid, in the handling of which much caution should be exercised. It is very volatile, and its vapor, as well as the liquid itself, inflammable. When employed for removing grease, or other stains from clothing, gloves, etc., it should never be used at night, nor at any other time near a fire. *Ether* is another dangerous liquid, and in other than the physician's hands it had best not be employed in the household. *Alcohol* must also be used with great care, especially at night.

**CLEAN THE CISTERN.**—Rain water, though very pure as it falls from the clouds, takes with it more or less impurity from the roof upon which it is caught and the pipes through which it passes to the cistern. There is a constant inlet for impurities, but no outlet, and these falling to the bottom accumulate to such an extent, that the water in time becomes tainted, and sometimes decidedly unhealthful. When the water is low, a cistern should be cleaned, and this, at least, as often as once in a year.

**CARE OF ASHES.**—In the disposition of ashes, at least two points should be kept in mind, *safety* and *cleanliness*. If the ashes are from wood, no sifting is necessary. They should, if possible, be removed from the stove only when cold, that no live coals may be in them. In case this can not be done, great care should be taken that no fire is dropped on the floor, and in all cases a deep iron pail should be used; with a closely fitting cover. Wood ashes should never be put in a barrel, or in any other wooden receptacle, the number of destructive fires that have resulted from a disregard of this caution is a fearful warning. Even when no fire is visible, there is still danger. The length of time for which a fragment of live coal, no larger than a pea, will keep alive, when covered with warm, light ashes, is something astonishing; it has been known to last thus for days. A pit of stone or brick, and fire-proof, should be provided for keeping ashes in a convenient, secluded place a short distance from the house. With these precautions there is little or no danger of these fires which, when left unheeded, are not rare in town and country. Besides, ashes are worth 25 cents a bushel, and are far too valuable to be thrown away. Coal ashes, though not so valuable, should be properly provided for, on the ground of neatness, if for no other reason. Nothing is more distressing than to see, as is too often the case, a pan of coal ashes in one place and a box, or barrel, running over in another. These will be sown broadcast by the winds on the snow or ground, to be tracked into the house at every step. Coal, that is, hard coal, is rarely burned so completely that it will not pay to sift the ashes to save the unburned coal contained in them. When the clinkers are picked out of the sifted portion it is quite as valuable as fresh coal. There are various sifters, which allow the sifting to be done without dust, and if the ashes are sifted daily, the task is easy. Coal ashes are of almost no value

as manure, but they are useful on heavy soils, just as sand would be, to lighten them; they make excellent paths and roads when mixed with earth, while for the earth-closet they are as useful as dried earth.

**REMOVING GLASS STOPPERS.**—What is more obstinate and provoking than a stopper that does not yield to the ordinary method of removal by the thumb and finger! If the fastening is due to the contraction of the neck around the stopper, it may be removed by heating the neck to expand it. The method of heating the neck of the bottle over a lamp may be dangerous, except in skillful hands. The same end may be gained—the expansion of the neck by heat—by passing a strong cord over or around the neck and moving the bottle rapidly along the string. One end of the string may be tied to a door knob, or other convenient object. The stopper is often cemented fast by the evaporation of a minute portion of the contents of the bottle. If it contain a syrup, for example, in pouring out a portion of it the neck, or a part of it, becomes wetted with the syrup; if the stopper be at once replaced there will be a thin film of syrup between that and the neck; upon standing awhile the water from this film of syrup evaporates, leaving the stopper cemented in with sugar. If the bottle holds a tincture, that will similarly answer to hold the stopper. In such cases the cement must be dissolved out. Such bottles have a lip to facilitate the pouring, and this forms a groove or channel around the stopper; by placing in this groove a little water, for syrup, or alcohol if a tincture, these will soon dissolve the cementing material, and the stopper may then be removed with ease.

**A COVER FOR A BARREL.**—When a barrel of flour or sugar is opened, the head should be taken out carefully, and the three parts hinged together,

Fig. 1.—THE BARREL.

by means of strong linen, glued on the sides, but not the edges of the pieces, or strips of leather, nailed on as shown at figures 1 and 2. The cover is fixed

Fig. 2.—THE COVER.

to the head of the barrel, by tacking one of the end pieces of the cover, to the chime of the barrel, and the other parts rest as they are laid down. This makes a good cover for barrels in the house, and also those used in the barns.

**HANGING UP COATS.**—A heavy garment, like an overcoat, if hung by the loop at the back of the collar, will soon stretch out of shape by its own weight. To avoid this, various devices have been made, some of wire, and others of wood. A piece of hard-wood, long enough to reach from the outside of one sleeve to that of the other, will answer the purpose; it should have a hole bored through the center, or a loop of strong cord to hang it by upon the nail or hook. Under-coats and vests may be hung in the same way. For the "best suit" this little matter is of considerable importance to all who desire their coats to not be full in the back of the neck, and therefore, out of shape.

**EATING SNOW.**—The practice, so common among school children, of devouring large quantities of snow and ice during the winter months, is to be discouraged. The blood vessels and nerves of the mouth and throat are chilled, often producing congestion, followed by cold in the head, and afterwards by more serious and deeper-seated troubles. A little piece now and then may not be objectionable, but the wholesale use of ice is decidedly so. Some school children seem to regard it as an article of diet, and as if it was the only thing to eat.

**GINGER COOKIES.**—1 cup Water, 2 cups Molasses, 1½ cup Lard, 1 tablespoonful Soda, 2 do. Ginger. A pinch of Alum, to be dissolved in the water. Flour enough to roll out soft; bake quick.

### Soldering Liquid.

In soldering tin-ware, especially in mending old ware, the use of Soldering Liquids will greatly help. There are several of these, the best is made as follows: Get any convenient vial about half full of muriatic acid; procure at the tin shop some scraps of sheet zinc; if you have no strong shears, let the tinsmith cut the zinc into strips narrow enough to enter the vial. Place the vial out-doors, or under a shed, and add a strip or two of zinc. A great bubbling or boiling will take place as the zinc dissolves; as one piece of zinc dissolves, add another, and when a piece remains without any action, or bubbling of the liquid, it is done. Fit to the lower end of the cork a piece of stick to reach into the liquid; after the liquid is perfectly quiet, cork it. In soldering, wet the place where the solder is to go, with this liquid; the drop or two that the stick will take up is enough. Do not get this liquid on the clothing, or on the skin, as it may irritate it and make it feel very rough.

### A Hanging Housewife.

To find a pin, *just when it is wanted*—and who cares for one at any other time?—is a small, but often a very valuable bit of information—and so with a long list of such other useful things, which are too frequently out of reach when wanted. A hanging "housewife," has some advantage over the ordinary work basket. It has a place; it can not be readily upset by a playful pussy, or dog, or roguish children, and it is more capable of being made an ornament to the room. It should supplement rather than replace the basket. The accompanying engravings, suggest a "housewife," that may be made at no considerable outlay for the materials, and is neat and handy. Its construction is simple, but in this matter, individual taste may be exercised, and as many pockets, etc., can be put in as desired. Some heavy cloth is selected as the back or framework, and this is bordered with fringes, and ornamented with initials, and other needle-work, tassels, ribbons, etc. Figure 1 shows the affair as complete, and hanging upon its hook, and an interior view is given in the second engraving. The fact that it folds up—or down rather—is important, both as regards beauty and cleanliness. The upper half, as it falls down, gives a neat and finished appearance, and at the same time shuts out the dust, which would otherwise collect in the folds.

Fig. 1.—THE "HOUSEWIFE."

Fig. 2.—THE "HOUSEWIFE" OPEN.

Important, both as regards beauty and cleanliness. The upper half, as it falls down, gives a neat and finished appearance, and at the same time shuts out the dust, which would otherwise collect in the folds.

### Hard and Soft Water.

Several correspondents write that their well water is "too hard for drinking," and inquire how it can be made soft. In a general way, waters are of three kinds; soft, hard, and mineral. If the water will mix readily with soap, without curdling, it is called soft. If, when mixed with soap, there are small white curdy particles floating in it, and when used for washing this curdy matter sticks to the hands, it is said to be hard. When matters dissolved from the soil are in such quantity as to give

a marked taste to the water, it is then a mineral water. The "hardness" of water is due to the presence of a very small quantity of mineral matter, most generally lime in some form. Soap is a Stearate of Soda, the Stearic Acid (an acid of fats) in combination with Soda. When this comes in contact with some Salt of Lime, the Stearic Acid, having a stronger attraction for Lime than it has for Soda, leaves that and unites with it, forming a Stearate of Lime, or Lime Soap. This, unlike Soda Soap, is not soluble in water, but when formed, it sticks to the hands, or to the fabrics washed, giving both a harsh hard feeling that is most disagreeable. This is in brief the science of the matter. All soaps are not Stearates, but some contain Oleic Acid in place of Stearic, hence are Oleates, and soft soaps have Potash instead of Soda, but in these cases, the action is the same as stated. The Lime in hard water is present in the form of the Sulphate (Gypsum), or the Carbonate of Lime (Limestone). But in the case of Carbonate of Lime, that is soluble only by the presence of Carbonic Acid in the water. When a very hard water is boiled and allowed to cool, a large share of the Lime leaves the water, and will in time settle to the bottom of the vessel. This happens to some extent if the Lime is in the form of Sulphate, because that is less soluble in boiling than in cold water; in the case of the Carbonate of Lime, the heat drives off the Carbonic Acid which held it in solution, and nearly all of that is deposited. If the excessive hardness of the water from our correspondents' wells is due to the Carbonate of Lime, boiling, before using, would remedy the difficulty, but this would not answer in case the trouble is due to the Sulphate, as only a portion of that would be deposited, and there is not, so far as we are aware, a practical remedy that will leave the water fit for use. The better way will be to make use of filtered rain-water; our hawk volmres give a number of filters, either separate, or attached to cisterns. At first, those who have been accustomed to hard water, do not like filtered rain-water, finding it flat and tasteless, but in some cases under our observation, the persons after a while preferred it to any other water. Those who live in the country, especially, can by a little painstaking, have rain-water in a state of great purity. The roof water-pipes and cistern should be kept clean, and by the use of a filter, as an extra protection, the best of drinking water may be thus enjoyed. Even if the taste is less agreeable, it is better to make use of it than to risk the diseases that are apt to result from the continuous use of water highly charged with Lime.

### Scrape the Feet!

Every careful house-keeper, with an eye to first causes, is much interested in the way feet—or rather feet-coverings—come in from out of doors. If boys did not have muddy boots—the cares of the house would be much lessened. But boys are not the only ones that "bring in the dirt." Men-folk are often very forgetful of the amount of work they may make by not attending to the simple matter of cleaning their boots and shoes. Every door-step should be provided with a foot-scraper, and a brush or broom, and every one, as he comes in, should take the time to use them before appearing on the carpet, or clean floor. If a regular scraper—one made for the purpose—is not at hand, one can make one from a bit of hoop-iron, which is to be placed on a step or edge of the porch in a convenient place. It is well to provide a "mud-mat," which is simply strips an inch or so square—fence pickets will answer—screwed to three or four cross-pieces, an inch apart; or a more elaborate one can be made by stringing the slats upon fence wires, as shown in May, 1876. One, with muddy boots, is very apt to stamp and rub them on the steps or floor of the porch; a mud-mat will clean them more effectively, and save the porch hard wear. A very excellent mat may be made by boring holes in a board, and drawing corn-husks through the holes. Careful persons change their foot-gear when they enter the house to remain any length of time, a custom conducive not only to neatness, but so greatly to comfort, that it is to be commended.

### A Very Convenient Solder,

to have always at hand in the house is often hawked at the fairs and elsewhere, and sold by itinerant peddlers on the street corners or from house to house. It is a very cheap article that should be kept on sale at the Family Supply Stores. It will pay a fair profit at 50 cents a pound. We see it frequently in the wholesale metal stores in the form of wire (about No. 15), weighing say an ounce to the

METHOD OF SOLDERING.

yard. It might be mailed to any point in the country for five cents a yard, if a few yards went together in a coil, and it would be a great convenience to those remote from a tin-shop; while very often one can quickly stop a leak in a tin vessel in a minute or two, and thus save time and the trouble and expense of sending to a tin-shop at all.—The mode of using is shown in the illustration. The tin dish, pan, platter, boiler, or other article, is heated over a candle or lamp, or a coal from the stove, at the point of leakage, and the solder-wire rubbed over the hole until it melts, when, by a little dexterity soon acquired by practice, a drop of the solder will be left smoothly over the opening. Too much heat is to be avoided, and if some of the solder runs through it can be pared or filed off when cold. The only other point is to have the solder touch and adhere to the tinned surface all around the leak. If the tin is very rusty for some distance around the opening, the solder may be made to "take" to the rusting portion by touching it with a drop of the soldering fluid mentioned elsewhere.

### An Ornamental Match Holder.

If all the different match-safes, and match-holders could be brought together, they would form a collection as varied as the different designs for cooking stoves, and washing machines. To the already numerous patterns, we add another, which may please those who like to make fancy articles, that shall be useful, as well as ornamental. The design is that of a suspended boat, and admits of a great variety, as the boat may be a miniature plain scow, a fanciful "shell," an Indian canoe, or something more elaborate. It is to be suspended by cords, plain or beaded, by ribbons, or otherwise. The boat may be made of wood, cardboard, or even of tin: if of the latter, it may be covered with perforated cardboard, upon which worsted patterns are worked. Whatever the material, it is intended that the exterior shall be ornamented, by small, bright-colored pictures, or in whatever manner fancy may suggest. At the bottom, or elsewhere, should be fixed a piece of emery paper, to furnish a place to scratch. The boat may have a partition amidships, providing two compartments, one for the unused matches, and the other for the burnt and useless. In some cases, a receptacle is made for the burnt matches, by suspending a second boat below the first, as seen in the above engraving.

A BOAT MATCH HOLDER.

# BOYS & GIRLS' COLUMNS.

## The Doctor's Talks.

Last month we were talking about Inertia, and it was there mentioned that a body set in motion can not stop of itself, any more than it can start of itself. That a marble set in motion by rolling on the floor would continue to roll, were it not stopped in part by the resistance offered by the air, and in part by that presented by the floor. Let us take, for illustration, besides a boy's marble, also a square block of marble, of the same weight, and the smooth table instead of the floor. You know, without trying it, that if you give both the ball and the block a push with the same hand, that the marble will roll quite across the long table, while the block will move but a few inches. If you think why this is, you will at once see that the block touches a very much larger part of the surface of the table than the ball, and that the rubbing of the two prevents it from going far. This obstacle to motion by the rubbing together of two surfaces

IS CALLED FRICTION,

a word that comes from the Latin word *fricare*, to rub. You know that the block will slide easier upon the smooth table than it will if there is a cloth upon the table, and more readily upon ice than upon the smooth table. In the case of the round marble, friction helps step that, as you know that it will roll farther on the smooth table than on the table-cloth, and upon smooth ice much farther than on the table. There are then two kinds of friction, Sliding Friction and Rolling Friction. Suppose you try to push a long wooden box along the bare floor. If this box weighs 100 pounds, you will have to push against it with a force equal to about 50 pounds before you can start it. You think that by turning the box upon its smaller end, which will present less surface, you can move it easier. Try it. Not a pound easier will it move. The amount of friction does not depend upon the size of the surface, but upon the pressure. That is one of the laws of sliding friction. There are others laws concerning friction, but we will not give them now.

### THE IMPORTANCE OF FRICTION

will be seen when we consider that *one-third* of the power of machinery is used in overcoming friction. Hence to reduce friction to the least possible, various contrivances are used. There is more friction between two surfaces of the same metal than between different metals. An iron shaft will run in a bearing of brass with less friction than in an iron one. If the wheel of our wagon does not run readily, we know that there is friction at the hub; we apply grease, and that diminishes the friction, the various articles need to reduce friction are called

### LUBRICATORS,

a word which, like friction, comes from the Latin, and means, to make slippery. A number of lubricators are used: oil, lard, tallow, soap, black-lead, and even water. But in many cases, what are called "friction wheels" are used, though the better name would be anti-friction wheels. An axle of a large wheel is made to turn upon two wheels placed together as seen in figure 1, which

shows an axle resting upon the rims of two wheels. As the axle turns, the wheels turn too, and the friction is only at the axles of these small wheels. It is common to hang a grindstone in this manner, as no doubt many of you have seen. Figure 2 shows the contrivance for a grindstone, the stone, however, is not there; what might be taken for the stone is two iron plates, which are made to screw up against the stone, one on each side; the friction wheels where the crank is are covered by a

Fig. 2.—FRICTION WHEELS FOR A GRINDSTONE.

guard to keep the clothing of the one who turns from catching, and also from getting soiled. The least known friction between two substances is between polished steel and some of the harder precious stones, from the cheap amethyst up to precious rubies and diamonds.

### "JEWELLED WATCHES"

are not watches ornamented with jewels, but those in

which the axles of the wheels run in jewelled bearings; even very common watches have some of the more important bearings fitted with cheap jewels. Knowing that so much pains is taken to remove, or overcome it, you may be tempted to say I wish there were no friction.

But that would be a hasty wish; if it could be granted there would be a queer state of things. Our wooden buildings and interior woodwork would fall apart, as it is only held together by the friction between the wood and the nails; you could not walk without slipping up; the vessels could not go to sea, for all their ropes would untwist; the locomotives could no longer pull their trains—indeed, the difficulties we some times find on an icy morning would be as nothing to it. This world is very well arranged as it is.... When you strike a ball that is at rest with your bat, the motion of the bat is imparted to the ball, and off that goes. If you strike with the bat a ball that is thrown towards you, you not only stop the ball, but, if you hit it hard enough you send it off in an other direction. This is one of the many instances that illustrate the

### COMMUNICATION OF MOTION.

If you place on the table one of two ivory balls of equal size, or even two marbles, and roll the other against it, if the balls strike fairly the one that is hit will move on, while the one that gives the blow will stop, it having given up its motion to the other ball. The same thing may be shown by hanging the balls by strings. A still more striking experiment is to take several elastic balls, as shown in figure 3. By drawing out the ball, *h*, to a short distance, and letting it drop to strike *g*, it will give up its motion to *g*, but that can not move, so it imparts its motion to *f*, but that is prevented from moving, and the motion goes on through all the balls until the last one in the row, *k*, is reached, and being free to do so, that flies off as far from the others as *h* was raised before it was let fall. Glass marbles are often used by boys, and these answer well for this experiment; as boys can not readily attach strings to the marbles, they can show the action nearly as well by placing two square straight-edged sticks near enough together for their edges to form a

Fig. 3.—THE ELASTIC BALLS.

groove for the marbles to roll along; as the marbles will only touch the corners of the sticks there will be but little friction. But this experiment, figure 3, not only shows that motion is communicated by one moving body to another, but it is one method of showing one of the important laws of motion, that

### ACTION AND REACTION ARE EQUAL.

If you strike the table with the hand, the table reacts, returns the blow with a force that makes it unnecessary for you to repeat the experiment. If you fire a bullet from a gun, the force of the gases formed by the burning powder pushes the bullet out with great force, but it also pushes the gun back with equal force against the shoulder, or as is commonly said

### THE GUN KICKS.

By making the gun heavier, the powder has to react upon so much more matter, the motion is felt but little.—If the gun be held firmly pressed to the shoulder, the recoil seldom hurts much; but if it has any distance to move back before striking the shoulder, it acquires a strong force, and strikes a much greater blow, just as a hammer pushed against a nail has little effect, but if moved a little through the air it acquires a strong momentous force, and drives the nail into the board.

### A Curious Time Trick.

Here is a rather neat trick, and one quite new to us. Let a person tell when he ate his dinner, and another, with certain conditions, can know when the same person took his breakfast, or arose in the morning, etc. Suppose

Mr. A. had his breakfast at a certain hour, as at seven o'clock, which he does not tell; but gives the hour that he ate his dinner, as at two in the afternoon. Add 12 to the hour given—in this case the sum will be 14. The person is then requested to count back on the dial of the watch or clock (it may be done in the head), beginning with the number or hour that he had his breakfast, and which he has not told. In this particular case it will be

A Picture Puzzle is a double one; it usually contains a scene in nature, with the lines so arranged, that after a little looking—or it may be that it will require a good deal of inspection—the object intended comes out, and ever after you can not look at the picture puzzle without seeing it. The one here presented, is perhaps too evident "on the face of it," to be much of a study; but nevertheless, it shows how the artist can, in some measure, hide one thing behind another, and it will serve very well to show how such pictures are made.

7, and as he counts to 14 he stops at the hour of breakfasting. Let us try it again. The boy rose at 8 o'clock (not very early for a smart boy), and had his dinner as late as 3 o'clock. Both of these hours are indicated by the hands on the dial. Being ashamed of his rising, we will suppose, he only tells when he had his dinner. Twelve is added to the 3, and we have 15. He begins at 3, with the rising hour in mind (8), and counts back on the dial until 15 is counted, and this comes to 8, the hour of rising, and his tardiness is exposed. The counting back is indicated by the figures outside of the dial. If you try it in all possible ways, the truth will out, no matter what the hour in mind is or the hour selected.

DIAL FACE.

### Our Puzzle-Box.

#### NUMERICAL ENIGMA.—BIBLICAL PROVERBS.

1. I am composed of 80 letters:  
The 12, 23, 49, 77, 44, 61, 18, 3, 23, 34, 38, 48, 62, 76, 26, 32, 33, 5, 64, 29, 70, 46, is a proverb of truth.  
The 67, 2, 20, 27, 37, 40, 63, 14, 43, 19, 49, 11, 16, 32, 1, 78, 1, 65, 8, 71, 66, 17, 22, 70, 4, is a proverb of caution.  
The 28, 1, 45, 33, 42, 13, 124, 73, 32, 20, 21, 69, 75, 10, 54, 45, 50, 2, 9, 25, 29, 48, 14, 39, 8, 40, 15, 63, 18, 35, 36, 33, 66, 56, 7, is a proverb of honesty.  
The 80, 60, 28, 55, 21, 23, 72, 31, 69, 19, 79, 32, 30, 15, 62, 15, 35, 51, 4, 59, 49, 38, 53, 6, 44, 78, 23, 33, 52, 41, 2, is a proverb of education.  
The 59, 141, 8, 63, 58, 21, 73, 47, 57, 10, 27, 74, 20, 34, 19, 68, 22, 37, 70, 12, 13, 69, 35, 73, 42, 16, 29, 43, 38, 28, 40, 41, 3, 26, 31, 46, 17, 25, 69, 44, 36, 54, is a proverb of reputation.

The whole is a proverb of Solomon. ISOLA.

#### NUMERICAL ENIGMAS.

2. I am composed of 40 letters:  
My 2, 9, 36, 7, 14, 5, 12, 20, was one of the greatest of military men.  
My 38, 31, 16, 9, 8, 33, 40, 21, 17, came from a foreign land to fight for American liberty.  
My 18, 11, 23, 3, 29, 20, 23, 1, 31, 38, will long be remembered.  
My 10, 22, 20, 19, 9, is the birth-place of the discoverer of America.  
My 35, 4, 17, 36, 9, 30, 24, we often think of with sadness.  
My 18, 28, 15, 23, 9, is one of the oldest nations on the earth.  
My 18, 14, 39, 6, 37, 34, was the founder of France.  
My 19, 13, 32, means away.  
My 16, 25, 26, 27, is a member of the body.  
My whole is an adage that all young folks ought to remember. KEN. C. HILL.

#### CHARADE.

A very little word, my first.  
Used constantly each day;  
A simple pronoun names my text,  
Though 'tis not "you" or "nay."  
And now from out some sacred spot  
Rises my solemn whole,  
To calm and fill the heart with peace,  
Or elevate the soul.

## CROSS-WORD.

My first's in the blossom but not in the tree,  
My next's in the ocean but not in the sea,  
My third's in the pantry but not in the shelf,  
My fourth's in another but not in yourself,  
My fifth is in finger but not in thumb,  
My sixth is in orange but not in a plum,  
My seventh is in cottage but never in a hut,  
My eighth is in acorn but not in a nut,  
My ninth is in shoulder but not in an arm,  
My tenth is in pasture but not in a farm,  
My eleventh is in village but not in the town:  
My whole is a poet of ancient renown.

## SCATTERED SQUARE.

(Make five or more square words from the following well-known verse of poetry, by taking four letters from the first line for the first word of the square; four letters from the second line for the second word; four from the third line for the third word, and four from the fourth line for the fourth word.)

Old mother Hubbard went to the cupboard  
To get her poor dog a bone,  
When she got there the cupboard was bare,  
And so the poor dog had none.

## HALF SQUARE.

- |                                   |                   |
|-----------------------------------|-------------------|
| 1. Is sure to come in the spring. | 3. An animal.     |
| 2. "Aft gangs agree."             | 4. A preposition. |
|                                   | 5. A measure.     |

## Pop Corn.

When there is a little party of children gathered together, to spend a pleasant winter evening, capital amusement can be had with a corn-popper, and some pop-corn. It is such fun to see the little hard grains, turn themselves inside-out with an explosion, as the popper is gently shaken over the hot coals. Only a few kernels of the corn are put into "the wire cage on a stick," and in a few seconds the popper is as full as it can hold of nice, fresh, hot pop-corn. Who does not like to eat it, and who can not eat just one more nice "pop"? It seems as if "there is always room for one more." Pop-corn is nice enough when fresh and alone, or with a trifle of salt to season it, but when mixed with enough warm molasses candy to make the grains pack into great balls, it becomes something very attractive in both appearance and taste. We remember one time being guilty of excessive eating of pop-corn—a good many have a weakness that way—and some friends, wishing to show an appreciation of our efforts, prepared a pop-corn ball about the size of our head—and put it on the table. We had pop-corn for nearly a week, and that of the nicest kind. There was no cotton in the center as was looked for—all solid, and of the best quality. Every child likes pop-corn, and we suggest that those boys who do not usually grow it, had better look around for some good sort for seed and next spring plant a small patch of ground. It tastes all the nicer, and perhaps pops better if raised by your own hands.—Try and see if you can not raise a good crop to pop.

## A Boy's Composition on Winter.

Winter is the time of the year when it is real cold. There is lots of snow, too, where we live, and most of the neighbors are drawing logs to the saw-mill and chopping wood. We draw our wood from the woods on a long bob-sled made to draw wood. There are horses to the sled, and I drive them sometimes, but usually hitch my new sled, which I got at Christmas, behind the load, and get tipped over sometimes. The last time when we were coming down the hill, and John made the horses trot, I went head over heels into the gutter, and John did not stop for me but just laughed.

Winter is also the time for going to school, and having a great time snow-balling at recess, and some of the big boys strike pretty hard sometimes. Some of us have built a snow fort, and when we are in it we feel safe unless they try to take the fort, when we have to run for our lives. The girls do not like snow-ball much, but get their faces washed in snow, which I think is just as bad. Winter is the time when the days are short and the evenings very long. The days are not more than half as long as in summer, and the nights are twice as long to make it all square, I suppose, but I never staid awake to see. Winter is the time when we have buckwheat cakes; and pretty soon we will begin to have early lambs, and take care of them in the house; at least we did last year. Grandfather says the winter of '37, I think he said, was the coldest he ever saw, but if it was much colder than last Threday night, it must have been "a regular snifter," as old Jim Cooper said. Winter is a good time to go visiting if it were not for the chores. Really the best part of winter is when it begins to get warm again, and the birds come back and the leaves begin to grow. I don't think we would, many of us, like to have winter all the while. We have enough to suit me.

## The Third Drawing Lesson.

In our first and second lesson we gave for practice figures that had only straight lines, ending with the table and chair. Such pictures, though they may be easy to draw, are not very pretty. It is when curved lines are present in the outline that an object is pleasing to the eye. We find very few bodies in nature that are entirely bounded by straight lines. The earth as a whole is nearly a sphere, not "flat like a pancake," as the ancients thought. A man would be considered crazy if he were trying to find a square pumpkin, or an animal with no curves in its outline.—To know how to form curves, is then one of the essential things in drawing most of the objects which we see around us. For the purpose of illustration, we have placed a number of things—as great a variety as possible—upon a small slate, which many of our young readers will doubtless copy upon their own.—If we could see all these sketches together, especially the first trials, what an interesting picture gallery it would be! The easiest object, and the one which most will take first, is the pear; it is about as simple a thing as could be selected, being easier than a circle, if the latter is drawn without anything to guide the pencil. It will be seen that straight lines do not take part in the outline of

lines first, and then fill in the others, by making the bottom first, and so on to the top. The jar is not so hard, but will require considerable time and much care, as it has a number of straight lines close together, and if they are crooked the whole will look badly. The Morning Glory will not be found very difficult after the outline of the flower is once made; by the outline is meant the outer edge of the upper flaring part. It may be the easiest to begin by making the lines which run like umbrella bows from the center, and finish with the rim. Here the attachment of the upper part of the flower to the tube is shut out of view by the portion which spreads

DRAWING LESSON UPON THE SLATE.

out towards the reader. The "pussy" will require some patience in the making of her eyes—but she will hold still until all are done with her. Begin with the head, then the neck, back, and legs. Put in the eyes and fix up the whiskers the last thing. The butterfly will be easy, so far as outline is concerned, but to put in the bars and dots on the wings much care is to be taken to get them of the same size and shape on the right and left wings; the beauty of the picture depends almost entirely on the markings. For some pupils the turkeys will furnish a subject for a whole evening, and if one of you spends several upon it will not hurt the turkey, and will do you good. Try and try, again and again, until it can be drawn in good shape in quick time. The face is the last part of the lesson, and in some respects the most difficult. Any one can put lines together so that an ordinary person will know it is intended for a man, but to arrange the lines to produce the likeness of some particular man is an entirely different thing. Probably this center-piece will furnish work—and pleasant work—for many pencils before the young draftsman are satisfied with their work. We may turn the slate over at some future day, and show what there is on the other side.

## Icicles—How are they Made?

If a person, upon looking out of the window, should say—as he might at this hour—"What large icicles are forming on the eaves of the barn!" one could tell pretty well what the weather is, and has been. What are icicles?—Perhaps some of you will answer: "They are sticks of ice, long—long enough for eaves sometimes—usually more or less ridged and rough, tapering down to a pretty sharp point—every body knows what icicles are!"—How are they formed?—Some say they grow, but do they grow as children do, or cats, or even corn or apples? Do they grow on the inside or the outside? How does an icicle start?—But to answer this question, is the weather freezing or thawing when these hanging sticks of ice begin to form?—Freezing, of course; but there must be water running down the roof and off at the eaves, to begin with. Icicles form then after a thaw, when the weather sets in cold and the temperature is below freezing. As the drops of water arrive at the edge of the eaves, or "the jumping off place," they become so cold that they can not jump but become solid. Along come some more drops, and spread out over those that have gone before and have frozen stiff, and become a thin film of ice, but the tendency to run down causes the stick of forming ice to lengthen out towards the ground by the water running down and freezing at the end. The water keeps coming down, and as it strikes the ice of the icicle it runs along, a film freezing all the time. Thus it increases in size and length by the constant freezing of layers of water on the outside. If the temperature is just a little below the freezing point, the icicle will be longer and more slender

No. 473. Illustrated Rebus.—Words of wisdom from a very wise part of a very old book. A little pleasant study will reveal a wholesome truth.

than when the change of weather is sudden and the cold is severe—they will then be quite short and "stubby." Some children are very fond of eating these cold hard sticks, but they are not good.

### One of the 'Ologies.

Boys and girls are not to be blamed for thinking that this world is full of pretty long words, and not only long, but hard ones to spell, pronounce, and understand. Not long ago, some little one, not so young but she knew a great deal about some things, thought that most of the "study books" were on some 'ology or other. She is

for investigation, and after a number of years of studying the various kinds, seeing how they differ from each other, time of ripening, time of keeping, and many other things, he should put all his knowledge of fruits into a book, what should we call the book? We might say this is So-and-So's book which treats on the different kinds of fruits, their size, color, taste, and keeping quality, etc., or we might simply say this is "Mr. So-and-So's *Pomology*."—Now if any boy or girl is trying to learn the names of the various kinds of apples and other fruits, by asking the father or mother, or by going to a fair where such fruits are exhibited, and remembering how this and that kind looks, its size, shape, color, etc., that boy or girl is

so hard to keep still—see him soon creep, and jump along the floor a few inches at a time until he found that for which he lives—a tender morsel, which had fallen from some child's dinner-basket, or been dropped on purpose for the fun that it would bring. A mouse in school, if allowed to have his own way, watched by happy children's eyes, but not knowing that he is observed, is perhaps the most fertile source of bad lessons that there can be; but it has the good side in that it keeps the pupils still. Yes! "as still as mice"—a stillness that a teacher feels, and will usually remove. Aside from the timid and quiet way in which he gets his spoils, which is cunning in an object so small as a mouse, there is the beauty of

THREE MICE THAT ARE NOT BLIND.

more or less right. We have Physiology and Lithology, Geology and Zoology, Philology and Entomology, Theology and Meteorology, Mineralogy and Anthropology, Ethnology and Psychology, but we need not give any more. These words end in *ology*, and this word, like many others in our language, comes from the Greek. The meaning of this termination, or ending, as you may please to call it, is *discourse* or *treatise*, a thorough explanation—a complete description "a telling about the thing." Let us look into this matter of the 'ologies by taking one; as, for example, *Pomology*. Children are more *Pomologists*—there is another big word!—than perhaps Anthropologists or Geologists, though I have known some very good young Geologists. What does *Pom* mean? we know a little about the rest of the word—it comes from the Latin language which the old Romans talked, and means *fruit*. If we put the meaning of the two parts of our word together, we get *fruit discourse*, or, in other words, a complete treatment of the subject of fruits. As soon as we see the meaning of the word it is not so hard—words look blank and hard when we do not understand them. Suppose some person has made a great study of fruits, as pears, apples, etc.; he ate them when a boy, perhaps loved the subject so much that he even went into his neighbor's orchard to get specimens

studying *Pomology*, and if the study is continued until thoroughly understood, will become a *pomologist*.

### The Merry Mice.

The bright little creatures, three of which are presented in the engraving, have had from early times a reputation for stillness, shyness, hatred of cats, and love of cheese. There is but little friendship between boys, "take them as they run," and the ordinary mouse—and to be fair we must "take him as he runs" too. You will have to take him thus in most cases if he is taken at all. But before we kill the little mouse—and we do not argue that he ought not to be destroyed—let us see if there are not some things about him that are interesting. Let us suppose each reader is so situated that a real, live mouse is in sight, and yet Mr. Mouse does not notice that he is being watched. This thought takes me back to that old, red school-house on the hill, so old and shabby that a tramp would prefer to put up in the fence corner than enter; a building where the walls were full of big holes and a host of friendly mice made many daily visits to get their supply of bread and cheese. Have I not watched him with his head at the hole and his sharp eyes, just like heads looking out from under his thin, upright, watchful ears, and then "holding in" with all my might—it was

his very self. A mouse that has been fortunate enough to enjoy a good living, is plump and pretty; his coat is shiny, his ears are clean, and his *moustache* (which by the way, means *mouse like* or *mouse-colored*) is long and well kept. A nice mouse of itself—if one could lose sight of how he has made himself look so by petty theft and midnight plunder—as an object of beauty, is worthy of our highest regard. He combines all the smartness of the fox, and the delicacy of the deer; the shyness of the antelope, and the wisdom of the heaver—and all in a little lump so small that he builds his nest in our deserted hoot, and rears a family before he is observed. It is an old story that these little creatures so troubled an old bachelor that, driven to despair, he went a long way to a very large city to procure a housekeeper that might be able to drive away the mice. Of the success of the undertaking we are not told—at least, I only remember that through some had arrangements, on the way home there was a great smash and a tumble down time generally. But this story as it is told only goes to prove that mice at heart are dreadfully bad. I would gladly call them good, if they were so; but "They climb upon the pantry shelf,

And taste of all they please;  
They drink the milk that's set  
for cream,  
And nibble bread and cheese."

Their whole nature must be changed before they can expect to gain the lasting friendship of man. Mice and men may have some things in common, but the mouse's best interests are not man's, and that which promotes the highest enjoyment of man is opposed to the well being of Mr. Mouse. There is an eternal warfare between them, and through that living instrument—the dread of every throbbing, civilized mouse's heart, the sworn enemy of the whole

mouse tribe—the cat—man may hope to keep this little wolf from the door. No one, it seems to me, can help admiring the mouse as to the form and texture of his being—his eye is bright, his fur soft, and his outline pleasing; but his disposition is bad. He comes when we do not want him, and goes only when he can injure us no more, or his own personal safety demands it. He looks better eating cheese in a picture than when in flesh and blood upon the pantry shelf. He is never to be trusted, and is not safe until he is dead, and even then it is our wish that he had died away from home. That he is closely related to the rat is almost enough to condemn him; but his own deeds are the ones by which he is judged. It is a sad fact that the mouse was filled with the spirit of adventure during the early Pilgrim days, and came to this country in those old ships to establish a colony in the new world, that is now as wide spread as the Continent. He has been very successful in the work of colonization; it has not been without its struggles and conflicts, and if the whole history of the subject was known it would doubtless be a story of trickery and cunning without intent to kill, on the mouse's side, and self-protection mingled with no little malicious bloodshed on the other—if honestly written by himself it would be "a plain unvarnished (mouse's) tale." UNCLE HAL.

### MARKET GARDENERS.

Fresh, Pure SEEDS for YOU.  
 Send for Garden Manual and Price List for 1880.  
**J. B. ROOP, Seed Grower, Rockford, Ill.**

### Asparagus---New Variety.

Smalley's Extra Early Defiance; 2 weeks earlier than Colossal, a larger, softer grass; far superior to all other varieties. One acre will produce more grass with the same treatment than 2 acres of Colossal. It is the best Asparagus grown, either for private use or for market. Two-year-old plants, \$5 per 100, \$30 per 1,000; send \$10 per lb. Address **A. SMALLEY, BOUND BROOK, Box 99, N. J.**

Peach Trees for everybody. Apples adapted to a wide range of climate. Small Fruits, etc. Price-list free.  
**R. S. JOHNSTON, Stockley, Del.**

## Three New Potatoes!

**Pride of America.**—In appearance and quality resembles the Snowflake, ripens a few days later; very productive, large size, an excellent keeper; flesh fine grained, white, and of superior quality.

**Matchless.**—A cross between the Early Rose and White Peach Blow. Tubers very handsome, generally round; skin, slightly russeted, pale red; flesh fine grained, pure white, and of excellent quality. A great cropper, an excellent keeper. Ripens with the Peerless, which it will supersede.

**Silver Skin.**—Also a cross between the Early Rose and White Peach Blow. Tubers medium to large, with few small ones. Skin smooth, silvery white, sometimes russeted. Flesh snowy white, fine grain, splendid quality, cooks through quickly. Free from disease, and an excellent keeper. It resembles the Peerless, but is more productive and of better quality.

Prices of each of the above, \$1.00 per lb., 3 lbs. \$2.50, by mail prepaid. By freight or express at purchaser's expense. ½ Peck, \$3.00; 1 Peck, \$5.00; ¼ Bushel, \$7.00; Bushel, \$12.00; Barrel, \$25.00.

For more complete descriptions and illustrations, see **Bliss' Illustrated Potato Catalogue**, which contains a descriptive list of all the new varieties recently introduced, with many other desirable sorts, beautifully illustrated. Centennial collection of 500 varieties. Also much useful information upon the cultivation of this valuable esculent. 10c. Address **B. K. BLISS & SONS,** P. O. Box 4, 129, 34 Barclay St., N. Y.

## FRESH, PURE SEED

Our New England-grown Seeds have secured an enviable reputation, and we again invite the attention of **Farmers, Gardeners, Florists**, and others to our new and select stock of every variety, which we offer at low prices. Our **Boston Market Vegetable Seeds** have a special reputation for excellence, and our stock of **Flower Seeds** is unsurpassed in all the choicest varieties. Seeds sent by mail to all parts of the country, and guaranteed to reach purchasers. New Catalogue for 1880 sent free.

**HOVEY & CO., BOSTON, MASS.**

My Annual Catalogue of Vegetable and Flower Seed for 1880 will be ready by January, and sent free to all who apply. Customers of last season need not write for it. I offer one of the largest collections of vegetable seed ever sent out by any seed-house in America, a large portion of which were grown on my six seed farms. Printed Directions for cultivation on every parcel. All seed sold from my establishment warranted to be both fresh and true to name; so far that should it prove otherwise, I will refill the order gratis. As the original introducer of the Hubbard and Marblehead Squashes, the Marblehead Cabbages, and a score of other new vegetables, I invite the patronage of all who are anxious to have their seed fresh, true, and of the very best strain. **NEW VEGETABLES A SPECIALTY.**

## STEEL BARB FENCE,

Solves the FENCE Problem by meeting all the requisites of

**THE PERFECT FARM FENCE.**

Every Land Owner

should not fail to examine  
the merits of this fence. It  
is cheaper than all others.  
Easiest handled, and in fact  
just what the people of the  
restless States have needed  
for years.

To All Inquirers.

It is an impassable barrier,  
yet harmless. Prohibits es-  
saying. It can be put up by  
any one, and is compactly put  
up for transportation. In  
fact, it is the only fence dog  
and wolf proof.

Cheaper than Wooden Fences. Imperishable when once in place. Indestructible by the  
Elements. Wastes no soil by SHADE. Has no Weedy Fence Borders. Shelters no Enemies  
of the Crops. A Protection at all seasons. It is easy of Construction. It needs no re-  
pairs. Accumulates no snow-drifts.

## A STEEL THORN HEDGE.

Impassable Barrier. Prohibits all Trespassing. It can not be destroyed by fire,  
wind, or flood.

100,000 miles of Barb Fence have been erected in 1876, 1877, 1878. Agricultur-  
ists, Herdsmen, Sheep Husbandmen, Ranchmen, Vineyard Proprietors,  
Orchardists, Nurserymen, Railroad Companies, Road Proprietors,  
and all owners and occupants of soil and areas to be protected.

Manufactured by Washburn & Moen Manufacturing Co.,  
WORCESTER, MASS., and 21 CLIFF ST. NEW YORK.

There is more  
service in this  
shaped blade  
than any other  
kind.

## THE KNIFE OF OUR DADDIES.

The older readers will remember when the "Congress Knife" was the favorite. It went somewhat out of fashion 20 years ago, but it is coming back again with some other good old things. The cut shows "Our Best," best finish, pearl handle, 3 blade. Price, \$1.50, postage free; same in 4 blade, \$2.00; or with ebony handle, \$1.00; and ivory handle, \$1.25.

Our "Old Fashioned" Razor  
Steel Jack Knife, 2 blade, 50 cents,  
or same extra heavy, 75 cents.

"Our Best" Pruner, \$1.00, and  
lighter ones for 50 and 75 cents.

All blades warranted, and replaced,  
if soft or faulty. Circulars free. Ad-  
dress,

MAHER & GROSH, Cutlers,  
Toledo, Ohio.

## THE MONITOR SEED DRILL.

This is the most complete and positive Seed Drill ever invented. It is radically different from and superior to all others. It is the only machine which measures and drops the seed with a positive motion, and exactly the same amount at each foot or yard. It has been tested by 6 years' use in Massachusetts, and was awarded the highest prize at the "Centennial." The "MONITOR" has been thoroughly tested during the seasons of 1878 and 1879, and heartily endorsed as a

**FIRST-CLASS MACHINE**

by Professor Geo. Thurber, of New Jersey, and by Jas. Vick, of Rochester, N. Y.

Agents Wanted.—For full descriptive circular and testimonials, address

THE MERRIMAC MACHINE CO., Newburyport, Mass.

The Ready Family Soap Maker: **LEWIS'**

# PERFUMED LYE

**98 Per Cent. Pure!**

**STRONGEST AND BEST LYE MADE.** This LYE is a FINE POWDER, and packed in cans with an ordinary slip-lid like our Baking Powder, so that any portion of contents of can may be used without spoiling balance. 12 pounds of Perfumed Hard Soap made in twenty minutes without boiling, — and your wash will be sweet and clean to the senses, without that nasty smell produced when using ready-made Soap or Soap made from other Lye. One teaspoonful will soften five gallons of hard water.

LEWIS' LYE is 28 per cent. stronger than any other Lye or so-called Rock or Ball Potashes.

MANUFACTURED ONLY BY

GEORGE T. LEWIS & MENZIES CO., Philadelphia, Pa.

**CHALLENGE FEED MILLS.**

Grinds three times as fast as any other mills. Always successful. Over 500 First Premiums and Medals. Over 15,000 in use. They do not clog or heat; grind 60 bushels per hour. All successful Iron Feed Mills INFRINGING OUR PATENTS. Beware: Buy none but the best. Remember the Courts have sustained our Patents. Also the best Wind Mills, Corn Shellers, Horse Power Wood Saws, Fanning Mills, and

## HAY &amp; STRAW PRESSES.

DERICK'S HAY AND STRAW PRESSES are guaranteed cheaper at price than any others as a gift or no sale. If inexperienced purchasers are confused by manufacturers of inferior machines who claim their presses are best, then order a press of each on condition that you keep the best, and advise all that DERICK'S PRESSES will be there. The absence of all others will then convince you that DERICK'S PRESSES are beyond competition. Grand Centennial and Paris World's Fair Prizes, and all the United States Fair Premiums for years past for DERICK'S PRESSES. Beware of presses infringing Derick's Pat. Press and Bale. Address, for catalogue,

N. B.—The attention of the public is respectfully invited to other advertisements of Hay Presses which have appeared in these columns, all of which make Derick's patent sectional quadrilateral bale bound lengthways, and by Derick's patent process and machinery, and some even have the check to use Derick's Continuous Hay Press patent, without which the operation must stop to tie and remove the bale. Derick has suits pending to enforce these patents, and will in due time prosecute every purchaser for \$10,000 damages. Meantime he earnestly remonstrates against this high handed piracy of his property, and warns the public against being swindled into partnership in a deal with unscrupulous characters. Why join a steal for the benefit of thieves and receive an inferior machine, when the same price will purchase a good one of the owner. While Derick bore the immense expense of introducing these improvements that are such a benefit to the hay interests of the country, these communists opposed him, and now propose to steal not only Derick's patents, but the capital represented by its introduction into use. Send for free copies of patents in proof of this.

P. K. DERICK & CO., Albany, N. Y.

## Improved Baldwin's American Fodder Cutter

The Simplest and Best! Only three Feed Gears! Cuts all kinds of feed, hay, straw, and corn-stalks with ease and rapidity. M. L. HOLBROOK,  
13 & 15 Laight St., New York.

containing a great variety of items, including many good hints and suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Continued from Page 50.

In justice to the majority of our subscribers, who have been readers for many years, articles and illustrations are seldom repeated, as those who desire information on a particular subject can cheaply obtain one or more of the back numbers containing what is wanted.

Back numbers of the "*American Agriculturist*," containing articles referred to in the "*Basket*" or elsewhere, can always be supplied and sent post-paid for 15 cts. each, or \$1.50 per volume.

**The German Edition.**—All the principal articles and engravings that appear in the *American Agriculturist* are reproduced in the German Edition. Besides these, there is a special department, edited by an eminent German cultivator. Our friends can do us a good service by calling the attention of their German neighbors and friends to the fact that they can have the paper in their own language, and those who employ Germans will find this Journal a most useful and acceptable present.

**Bound Copies** of volume 38, and of every previous volume back to Vol. XVI. (1857), neatly bound, with gilt backs, Index, etc., are supplied at \$2 each (or \$2.30 if to be sent by mail). See Publishers' Notes, 2d cover page.

**Clubs** can at any time be increased by remitting for each addition, the price paid by the original members; or a small club may be made a larger one at reduced rates, thus: One having sent 6 subscribers and \$7, may afterwards send 4 names more and \$3, making 10 subscribers for \$10.00; and so for the various other club rates.

**Terms to New South Wales, New Zealand, Australia, Africa, etc.**—To several inquirers. Under the latest revision of the Postal Union Regulations the price of the *American Agriculturist*, (either English or German edition), including postage prepaid through, will be covered by 7 shillings sterling per annum. This applies to the above countries, and to all others embraced in the General Postal Union. The simplest mode of remittance is by Postal Money Orders, payable in London, to the order of Orange Judd Company. These can be readily cashed in N. Y. City at a slight discount, which the publishers will cheerfully pay. For Club rates, (postage included), see our second cover page, and reckon 22 cents to the shilling sterling.

**Hens in Winter.**—If eggs are expected during the winter months—and they ought to be—the fowls must be kept warm and well fed. They will not bear crowding, a fact that is too often overlooked. Hens are naturally active creatures, and must have room to run and exercise themselves. The house must be kept clean, and an abundance of fresh air and pure water provided; also a constant supply of oyster shells or bones, broken fine.

**Packing Frozen Meat.**—Meat that has been frozen, as is often the case with pork and beef killed at this season, should be thawed out before being put into the barrel, as the hard frozen meat does not absorb the salt as it ought, and otherwise would do.

**Rolling Wheat After Sowing.**—This is a good time of the year to observe the effect of rolling the wheat ground and making it smooth after the grain is sown. If a light snow, or even a moderate one, comes, followed by a wind, it is carried to the fence rows, etc., and lodged wherever it can get a foothold, and if the field is rolled smooth the surface of the ground will be left bare and exposed to the severe cold, and more especially to the destructive influences of sudden freezings and thawings that may follow. If the surface had been left rough, much of the snow would have remained in place about the roots of the plants, and served as a protection against "winter killing."

**Milking.**—The thoughtful dairyman knows the value of a good milker, and will have no others in his herd. Much of the complaint made by men who have recently bought good milk cows and been disappointed in them, is due to the change of the milker. Careless milking is a fertile source of loss in dairying. The milk should be removed as rapidly as possible to the last drop, and at regular hours. With careful milking, kind treatment of the cows in all respects is of course understood.

PRONOUNCED  
the

## BEST PLOW MADE

by the

Northern Ohio Fair of 1879,  
State Fair of New York of 1879,  
State Fair of Michigan of 1879,  
and by the

Paris Exposition of 1878

when it competed with 187 other PLOWS, and received the GRAND GOLD MEDAL for being the BEST general purpose Plow in the world—an honor never before conferred upon a Hand Plow.

Is the MOST EASILY ADJUSTED and MOST PERFECT SCOURING PLOW ever invented, and the thousands that are in satisfactory use all over the land demonstrate the fact that no other CHILLED PLOW manufactured is equal in EVERY RESPECT to the "GALE."

For Circulars and prices, address

GALE MANUFACTURING CO.

ALBION, MICH.

## Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the *American Agriculturist*, from our record kept daily during the year, show at a glance the transactions for the month ending Jan. 13th, 1880, and for the corresponding period last year:

With the opening of the new year, business in Bonds and Stocks has been quickened by the restoration of ease in Money, which had been quite stringent through the last few weeks in December, chiefly because of the preparations, then in progress, for the 1st of January interest and dividend disbursements, the aggregate of which has been very liberal, thus reflecting, in part, the successes of the past year, in the industrial and commercial lines—the promise of which for the year now fairly entered upon is viewed as even more encouraging.... Produce and

Merchandise interests have shown a fair degree of activity, for the season. Metals have been the prominent feature, in the way of renewed and very decided buoyancy in values, through the unusually extensive operations, especially in Iron, Iron and Steel Rails, and Tin, for prompt and forward delivery, closing in favor of sellers. Hardware has been attracting more attention. Boots and Shoes have had an increased call for Spring styles. Hides have been less freely dealt in but have not varied much in price. Leather has been quite brisk; Sole having met with a ready sale, but at some slight reductions in quotations, under more liberal offerings. Seeds, Hops, Hay, and Straw have been very moderately sought after. Dry Goods have been in fair request, and held with confidence. Naval Stores have been more active and quoted higher, but closed less firmly. Petroleum has further yielded in price, on more urgent offerings, without leading to remarkable animation in the dealings, for early or future delivery.... Provisions have been in more demand, largely in the speculative line, on a fluctuating market, closing, as a rule, with more firmness. Lard has recently attracted more attention from shippers, particularly Western Steam, for the Liverpool market. Butter has been in good request at generally full figures. A livelier inquiry has been reported for Cheese, which has been advanced rather sharply.... Cotton has been fairly active, almost wholly in the option line, but at variable prices, leaving off with an upward tendency.... A fair demand has been reported for Wool, prices of which have been remarkably well supported, in instances showing a gain, since our last, and closing quite firmly, on comparatively limited supplies, which, it is apprehended, will be found inadequate to meet the requirements of consumers, up to the incoming of the next clip.... Tobacco has been quoted steadier, on a freer movement, in good part for shipment.... In the Breadstiff line, a notable reaction has occurred, since our last, from the buoyancy of the preceding month, values suffering serious depression, through the falling off in the export demand, as reflecting the heaviness in the foreign markets, the extraordinary accumulation of stocks on the seaboard, and in the interior, embracing the hoards at lake ports, in transit, and on the seaboard—at latest dates, 29,620,000 bushels;—of Corn, 11,500,000 bushels; of Rye, 1,136,000 bushels; of Barley, 4,334,000 bushels; and of Oats, 3,074,000 bushels, against, on December 13, an aggregate of 28,688,500 bushels Wheat, 10,079,400 bushels Corn, 1,162,000 bushels Rye, 4,663,600 bushels Barley, and 2,672,200 bushels Oats; and the baneful influence of speculative manipulation, which has arrested the outflow of produce from our ports, and led to a further material decline in ocean freights, which on Grain fell to 3d. per bushel by steam for Liverpool (though rallying near the close to 4d.), and 4s. @ 4s. 3d. per quarter, of 480 lbs., by sail for Cork and orders, and proportionately to other destinations. Home trade dealings have also diminished in value. At the close, the advantage, almost throughout the market, was unmistakably in favor of buyers, especially in the instances of Wheat, Oats, Rye, and Flour. Wheat was pressed for sale at the extreme close, and Winter grades, under the pressure, receded, on Monday, 12th of January, 2@3 cts. a bushel on an active but feverish market, leaving off with a downward tendency. The purchases of Wheat, as reported on that day, were to the aggregate of over 1,450,000 bushels, of which only about 140,000 bushels were for early delivery; the bulk of the transactions having been in the option line, and these options exclusively on the favorite grades of No. 1 White and No. 2 Red, the February and March deliveries now meeting with most favor, as postponing pay day to the furthest, and thus extending the privileges of speculative operators. Spring Wheat has recently entered to an unusually limited extent into the daily sales,—the views of buyers and sellers having been too wide apart to admit of activity. In sympathy with Wheat, Flour, Rye, and Oats gave way in the latest dealings, and closed weak. Corn participated in the reaction, but suffered less severely, and for early delivery, hardened a little, in the final movements, which were, in good part, on the export account.

**Eclipses for 1880.**—There are to be six, namely: (1) A total of the sun, Jan. 11, visible through portions of Utah, Nevada, and California. (2) Total of the moon, June 22, invisible in eastern portions of the United States. (3) Annular eclipse of the sun, July 7, invisible in North America. (4) Partial of the sun, Dec. 1, visible only in the Southern Hemisphere. (5) Total of the moon, Dec. 16, invisible in the eastern United States. (6) Partial of the sun, Dec. 31, visible in eastern United States. Thus the last day of the year brings the majority of our people a partial eclipse of the sun, and the only visible one.

**The Ice Harvest.**—The time for filling the ice-house will soon be over, and the harvest of ice should be made at the earliest day. To those that have never had the convenience, nor practised the economy, of a supply of ice for the hot months of summer, let it be said that it pays, and a house built now will not be too late.

**Salt Marsh.**—"P. W. H.," Aransas Co., Tex. Unless you can, by means of tide-gates or otherwise, control the inflow of salt water, you can make no valuable improvement in the quality of the grass produced. If the water can be excluded, Orchard-Grass, Timothy, and other "tame" grasses may be sown after the rains have freshened the surface. If this can not be done, encourage the natural grasses of the marsh by removing brush and other plants than grass, so far as practicable, for the natural growth is of far more value than is generally supposed, not only for bedding, but for feeding.

**The Western N. Y. Horticultural Society.**—There is no Society whose meetings we have a stronger desire to attend, or whose published proceedings—always brought out promptly, by the way—we read with more interest than this. Its meetings are held at Rochester, one of the great horticultural centers of the country, and when the cultivators from all the western parts of the State meet those belonging in that city, they form a gathering that, for practical knowledge of the subjects they discuss, can hardly be equalled elsewhere in the country. The meeting this year was held after this number went to press (Jan. 28th), but it is safe to say in advance that the proceedings were worthy of the occasion, it being the 25th anniversary of the organization of the Society; a quarter centennial celebration, demanding an extra effort on the part of the members.

**Where can Cranberries be Grown?**—"A. G. S.," Fayette, Iowa, has a piece of springy ground on the banks of a river, usually overflowed in spring, and is wet most of the season, and thinking that Cranberries may be grown there, asks us how to set about it. We can best answer this and other similar letters by giving the essentials in Cranberry Culture. The Cranberry plant, or vine, will live almost anywhere when once established, but for its profitable culture, there are certain essentials, in the absence of either one of which no cranberry-grower would undertake it. The soil must be either peat or muck, so situated that it may be drained for 18 inches below the surface, and an abundance of water at hand so situated that the ground may be flooded to the depth of some inches at once—added to these there must be at hand a supply of pure sand, enough to cover the whole surface of the bed for an inch or two. Without these success can not be hoped for, and it is not always realized when these are all present, as there are various accidents and troubles that may defeat the cultivator.

**Poplar Sprouts.**—S. Lea, writes that at the base of his poplar trees, there are some shoots, and he would like to plant them if they will grow, but they have no roots. He wishes to know what to do and how to do it. A poplar will grow almost as well without roots, as with. Cut them any time before the buds start, as small as a lead-pencil, or as large as the arm, and six inches or six feet long, set them out or drive them in where they are wanted, and they will attend to the rest of the work.

**Cannot Tell.**—"A Reader" asks why the vine of the bean turns one way and that of the hop in the opposite direction in their twining around the supports. Of course it is not very satisfactory to say it is the nature of each to climb in its own way—but that is about as far as we can go. Why will a chick run towards the hen that clucks for it, though it be for the first time, and the hen is not in sight? There are many things in nature that are beyond any exact explanation.

**Pleuro-Pneumonia** has broken out in New Hampshire, and the Governor has appointed a Board of Commissioners to investigate the appearance of the disease. A number of cattle have died at Haverhill in that State, and grave fears of its spreading are entertained.

**Corn Nubbins for Kicking Cows.**—There is an old farmer in Vermont who buys all the kicking cows he can find, and cures them with kind words, abundant use of the currycomb, and feeding of corn nubbins.

We are at a loss to decide which of the three agents is the most important, but think there is more in the first two than many may think. Harsh words and blows would more than overcome the soothing influence of the nubbins. Even cows can be influenced by example.

**Pressure on a Cistern.**—"T. B. P." If a cistern is empty, and the ground full of surface water, the pressure will certainly be considerable, and may be dangerous, if the cistern is not well constructed. If it is made of the shape of half an egg, the pressure will not injure it, that being the strongest possible form. If it is round with a flat bottom, the sides will be sound but the floor may be burst in. In such cases it would be well to provide against the danger by making the cistern of the strongest shape, and laying the bricks in the most substantial manner.

**The Bradshaw Plum.**—"J. P. W.," Fennville, Mich., asks us to give the merits of this plum, as it (the tree we suppose), is being offered for sale in his section. The Bradshaw is a fairly good, large, blue plum, ripening in August. In making a selection of 10 varieties, in the order of quality, we should not include the Bradshaw. In selecting 10 for profitable market culture, this would be included, and stand towards the head of the list. If offered as being "Curculio proof," or "Black-Knot proof," or remarkable in any other way, it is misrepresented.

**Fertilizer for Cotton.**—"J. R.," Kaufman Co., Texas. Peruvian guano is one of the best fertilizers for cotton. There are special manures made for this crop by the manufacturers of fertilizers, whose addresses may be found in the advertising columns; these fertilizers are cheaper than guano, and sometimes more effective, being richer in potash, the element that is most needed.

**Book on Cotton Culture.**—"R.," Lawrence, Texas. The most modern information about cotton culture is contained in the Manual of Agriculture by E. G. Wall, of Mississippi. The culture is very simple, and a whole book is hardly necessary to tell all the story.

**Chalk and Water in Milk.**—The daily city papers often call attention to the quality of the milk furnished to city customers. There is abundant reason for doing this, and they can not too frequently insist, that milk must be furnished just as it comes from the cow. But these articles lose much of their force by implying, indeed some of them directly asserting, that a mixture of chalk and water is served in place of milk. This is absurd; the most skilled manipulator can make no mixture of any form of chalk, that will be no more dense than ordinary milk, from which the chalk will not completely settle, upon standing for a few hours. We doubt if there was ever a pint of milk sold in N. Y. City, in which chalk was used as an adulteration. In London, milk and other adulterations were carried to such an extent, that Parliament had the matter investigated some years ago. Doct. Hassall, who was officially connected with these examinations, and has probably examined more samples of milk than any other person, says of chalk and starch in milk, while he admits that they may be very rarely used, that "It has not happened to ourselves to meet these substances in milk." Wanklyn, also of London, in the most recent work on the "Analysis of Milk," says nothing about the occurrence of chalk. The fact is, the most serious adulteration of milk is with water. Besides the addition of water, milk is impoverished by the abstraction of cream. These two, the taking off of cream, and putting in water, are the worst that happen to city milk, and these are bad enough. It diverts attention from these real troubles, to talk about improbable, if not impossible "chalk and water."

**Gold and Silver.**—The United States produced \$32,529,920 of gold and \$33,623,812 of silver during the year 1879. Nearly the whole of the gold, except 4 millions used in the arts, has gone into employment as money, and about two-thirds of the silver has passed to the mint. In addition to the production, we have imported \$75,000,000 in gold, while the exports of it have been almost nothing. It has been a golden year for us.

**Mending Rubber Boots and Shoes.**—A number have asked how rubber boots and shoes could be patched. Of course any cement used for this purpose must be elastic, and the only thing suited to the work is a solution of rubber itself. Unfortunately, rubber is soluble in but very few liquids, and these are either costly or dangerous to have about on account of their volatile and inflammable character. Probably the best solvent of rubber is Bisulphide of Carbon. (See "A Wonderful Liquid," page 453, November last.) We dislike to publish a recipe that we have not tried, and rarely do so; the following, commended for patching rubber, we have not used for that purpose, but have used it for cementing other articles, and have reason to think it will answer for that. Take one part of Rubber, three parts of Gutta-Percha, and eight parts of Bisulphide of Carbon. The Rubber and Gutta-Percha must both be pure; manufactured or vul-

canized will not answer; both should be cut fine and put with the Bisulphide in a wide-mouthed bottle with a tight cork. They will require a day or so to dissolve, and will need thorough stirring to make a smooth mixture. Recollect that the Bisulphide and its vapor will take fire very readily, and the greatest caution must be used. Moreover, it smells horribly. The rubber to be joined must be perfectly free from grease, and the parts coming in contact should be rubbed with fine sand-paper. When the patch is put in place it should be held there, by winding a string about it, or in any other manner that will keep it under pressure until the cement is hard.

**A Shell in a Tea-Kettle.**—"H.," says in a visit to the shore of Long Island Sound, he saw the house-keeper put a clean clam-shell or oyster-shell in her tea-kettle to prevent a crust from forming on the inside, and wishes to know if it isn't "an old woman's whim."—Not at all—but founded upon correct scientific principles. Some hard waters deposit, on being boiled, the Carbonate of Lime to which their hardness is due. In time this gradually accumulates and lines the interior of the tea-kettle; we have seen such a crust two inches thick. A shell, which is Carbonate of Lime, is placed in such water, when the water is heated the Carbonate of Lime it contained is deposited; it is in accordance with "the nature of things" that its minutely divided particles should aggregate themselves upon the shell, which is of the same material as itself, rather than upon the smooth iron surface of the kettle, thus keeping the kettle clean.

**Treatment for Garget.**—"F. S. C. H.," Lawrence, Mass. Garget consists of congestion of the udder, and it is not always caused by overfeeding. Sometimes it may result from a poor condition, and often occurs in poorly fed cows from want of sufficient vigor to control the circulation evenly. The disease results also from cold, excessive exercise, bruises, lying upon cold ground or floors without sufficient bedding, nervous excitement, or any disorder of the circulation which may throw undue pressure upon the glands of the udder. One-quarter or the whole of the udder may be effected. Thus it is readily seen that a specific remedy that will meet all cases can not be given. The cause must be discovered and the appropriate remedy provided. Generally, there is fever, and a dose of 12 ounces of Epsom Salts will tend to reduce that and lead to a recovery; the Salts will also act as an alternative upon the digestive organs, and will be useful in this case also. Accompanying remedies should be bathing the udder with warm water, injecting a solution of Soda to dissolve the curdled milk, or applying Iodine Ointment, which may be had at any drug store, externally to assist in absorption.

**Agriculture in France.**—The French Legislature has made the study of agriculture one of the regular branches to be taught in her public schools. A familiarity with the growth of crops, etc., is seen by that Republic to be as important as the fact that the earth is nearly a sphere, or the sun is between 93 and 95 millions of miles away from us. But where do they find competent teachers?

**German Ivy.**—Nothing in the way of living plants adds so much to the cheerfulness of a room as healthy vigorous climbers; and all things considered—ease of culture, rapidity of growth, grace and delicacy of form—the German or Parlor Ivy may well take a leading place.

**Celery.**—The complaints that come to us of the failure of celery to keep this winter show that the trouble is general. "W. H. B.," Waterbury, Ct., thinks that his trouble was due to late planting, but as he does not say when his was set out, we can not judge. But in general it is not necessary to go beyond the unusually warm weather to find a cause. Celery will grow at a very low temperature, and the weather has been for weeks at a time so mild that the plant would grow. Growth in the trenches is fatal, for its roots being out of the ground, whatever growth takes place at the center, must be at the expense of the other stalks, which become hollow and flabby. Besides this, in such a mass of vegetable matter, the warm weather will soon induce decay. Lovers of celery can congratulate themselves that statistics show that such a winter as we are now having is rare.

**Initials** in some cases, will answer instead of full names, but not in the U. S. Post-Office. Had we written out a rule, that we were requested to send "by letter," placed it in an envelope and directed it to "H. B. J.," Dayton, Ohio, it is very likely that it would be in the Dead Letter Office. No doubt the writer of the letter, signed only by the above initials, thought we were not very obliging to refuse him a small favor, and we hope he will now learn why we were obliged to do so. "A. C.," of "Stmga," will also learn why his postal had no reply. By aid of an imperfect post-mark, we could make out that the place was St. Marys, Ga., but as there was nothing to help us make out the A. C., we were unable to answer.

**Steel Calked Shoes.**—If horses fail to stand in slippery places it will be because their owners fail to provide them with some of the several excellent devices to aid them. The Forged Steel Calk Horse Shoe, made by the Bryden Horse Shoe Co., has several points to commend it. The toe calk is very long, and with the others so placed as to give an even bearing to the foot. The inside of the shoe is of such a form as to prevent stones and other matters from catching in it, and the shape of the crease shows excellent workmanship and attention to details. The list of those who have used the shoe with approval includes the names of some of the eminent horse owners in the country.

**Coloring Butter and Cheese.**—"G. T. S." The coloring of cheese, to meet the notions of certain markets, is very common; to color butter in winter, sufficiently to restore the lacking color, is regarded as legitimate by some of those who make the highest priced product. So long as a perfectly harmless vegetable coloring matter is used no harm can come of it. The color used is Annatto in some form; this is prepared from the pulp that surrounds the seeds of a South American shrub or small tree. The seeds are put into water and fermented, the liquid is poured off and evaporated to a pasty mass, about the consistence of putty; this is made into rolls, covered with some kind of leaves, and sent to market in baskets. Annattoine is the coloring principle separated from annatto, and is in a much more concentrated form. Annatto is sometimes used for dyeing cotton, but the color is not very fast; its chief consumption is in the dairy, and though the amount used by each one is small, the aggregate is large. The principal importer is Mr. L. E. Ransom, of New York, who also prepares it in the form of a butter color ready for use. There seems to be a number of methods of writing the name: annatto, annatto and arnotto being used, and sometimes it is called roucou.

### Catalogues Received.

#### SEEDSMEN.

BENSON, MAULE & Co., No. 223 Church Street, Philadelphia, Pa., send an illustrated list of farm, garden and flower seeds, implements, etc.

B. K. BLISS & SONS, No. 34 Barclay Street, New York, give their catalogue a quaint exterior in Japanese style. The interior shows the usual number of novelties in vegetables and flowers.

WM. E. BOWDITCH, 645 Warren Street, Boston, Mass., sends his wholesale list and retail flower seed catalogue.

FRANCIS BRILL, Mattituck (L. I.), N. Y.—Wholesale list of seeds grown by himself.

W. ATLEE BURPEE & Co., No. 221 Church Street, Philadelphia, Pa., send their "Farm Annual," which, besides being a catalogue of seeds of all kinds, includes stock and implements.

A. D. COWAN & Co., No. 114 Chambers Street, New York, send a very full, neat and clear list of farm and garden seeds and appliances.

D. M. FERRY, Detroit, Mich.—The full and profusely illustrated list of what is said to be the largest seed house in the world, gives views of their new store, the floors of which have an area of nearly five acres!

L. W. GOODELL, Amherst, Mass.—Illustrated list of seeds, bulbs and flowers.

HENRY NUNGERSSER, No. 83 Avenue D, New York.—Wholesale list of grass and forest tree seeds.

PLANT COMPANY, St. Louis, Mo.—Very full in seeds of all kinds. An Almanac, a Gardener's Calendar, and useful garden instructions—a treatise as well as a catalogue.

J. B. ROOT & Co., Rockford, Ill. It keeps up its interest in giving pleasant talks about garden matters.

ISAAC F. TILLINGHAST, La Plume, Lackawanna Co., Pa., makes of his catalogue a quarterly called "Seed Time and Harvest." The first number promises well.

E. WYMAN, JR., Rockford, Ill.—Full and neat, with sensible directions for culture.

PETER HENDERSON & Co., No. 35 Cortlandt Street, New York.—As usual, this bears the title "Everything for the Garden," and as it includes Peter Henderson's plant list, its title indicates the contents. Richly illustrated.

NANZ, NEUNER & Co., Louisville, Ky.—A full and illustrated list of seeds, bulbs, plants, etc.

#### NURSERYMEN.

J. L. DILLON, Bloomsburg, Pa.—Small fruits, with directions for culture.

LESLIE & McCUNE, Ipava, Fulton Co., Ill.—General list of orchard and small fruits and evergreens.

J. R. LONG, Columbia City, Ind.—Small fruits.

J. D. MOSBY & BRO., Richmond, Va., at the Richmond Nurseries, offer a full stock of fruits, including a number of varieties originating in the State.

J. F. NOBBER, Oswego, N.Y.—The leading Strawberries.

E. & J. C. WILLIAMS, Montclair, N. J.—Small fruits, ornamental stock, seed potatoes, etc.

#### FOREIGN CATALOGUES.

H. L. CHRESTENSEN, Erfurt, Prussia.—Dried flowers, dried and other grasses, and winter bouquets.

DAVID CLARKE, Brisbane, Queensland, Australia.—Quite a volume of seeds, trees, plants, implements, etc.

#### MISCELLANEOUS.

E. F. BROCKWAY, Ainsworth, Iowa.—Poland China Hogs, Poultry, with artichokes and chufas to feed them.

A. & T. BROWN, 57-61 Lewis Street, New York.—Shafting, pulleys, etc. Excellently illustrated.

JAMES LEFFEL, Springfield, Ohio, makes the Buckwater Portable Steam Engine and the Leffel Turbine Water Wheel. The catalogue of this Turbine is a wonder, having nearly one hundred large pages in which a profusion of full page engravings make the wheel so interesting that one at once wishes he had use for one.

ANDERSON REFRIGERATOR LINE MANUAL.—Aug. F. Higgs, manager of the above line, which runs its cars over various routes, publishes its business in a neat pamphlet, in which are given most useful directions for handling all perishable articles.

L. L. REED, Auhurn, Ohio.—An illustrated list of thoroughbred pigs, sheep, poultry, etc.

### BLOOMINGTON NURSERY,

Established 28 years—600 Acres—13 Greenhouses. The following are now ready for distribution—New General Descriptive Catalogue, 10c. New Plant Catalogue and Price List free. Address

BAIRD & TUTTLE, Agents, Bloomington, Ills.

## 20 Flowering Plants \$1

BY MAIL FOR

Prices Greatly Reduced. Our new instructive Catalogue describes all the leading Plants, Bulbs and Seeds. It is the cheapest price-list ever offered. Free to all. Send for it to THOS. ELVERSON, Hillsdale Greenhouses, New Brighton, Pa.

### FIRST CLASS TREES AND PLANTS At Very Low Rates.

Apple Trees, 15c. each; Standard Pear, 30c. each; Dwarf Pear, 20c. each; Strawberries, Raspberries, Blackberries, and Grape Vines, by the doz., 100, 1,000, or 10,000. Extra large stock of Sharpless, Miner's Proline, Albany, and other choice and standard Strawberries, Queen-of-the-Market Raspberry. Send for circular and see low quotations.

S. C. DE COR, Moorestown, Burlington Co., N. J.

Owing to the Failure of the Music House of Earlebach & Co., Germany, we purchased their entire stock of Musical Instruments, and offer them at half cost to make.

**Paganini Violin.** Celebrated for fine tone and finish. Italian strings, ebony pegs, inlaid pearl tail-piece, fine long bow with ivory and silver frog, in violin box. Book of Instruction, with 568 pieces choice music, including all the music from Paganini. By express for \$3.50. More than satisfaction guaranteed, or money refunded. A better violin cannot be purchased elsewhere for \$10.

We send, postpaid, with Words and Music, 100 Comic Songs for 40 cts.; 100 Sentimental Songs, 40 cts.; 100 Popular Songs, 40 cts.; 100 Irish Songs 40 cts.; 100 Ethiopian Songs, 40 cts. This opportunity to get a fine instrument for so small a sum has never been offered before. Do not delay; order at once, and secure the greatest bargain known. Address all orders, G. H. W. BATES & CO., Importers, Boston, Mass.

## POTATO BUG. COTTON WORM. CANKER WORM.

### THE BEST INSECTICIDE EVER USED.

## London Purple.

(Trade Mark.)

Sold by all Wholesale Druggists and Stores throughout the United States. It not obtainable of nearest dealer, send direct to sole manufacturers, **HEMINGWAY'S LONDON PURPLE COMPANY (Limited), 60 Mark Lane, London, England.** 90 Water Street, N. Y. P. O. address, Box 990.

A. R. WHITNEY, Franklin Grove Orchard and Nurseries, Lee Co., Ill., writes: "We have had the Canker Worm a long time, and have done it with your LONDON PURPLE. We put in about three-fourths of a ton of LONDON PURPLE to 44 gallons of water, and applied with a force pump. It is better than Paris Green, as the particles of LONDON PURPLE adhere to the leaves and Paris Green does not."

**CHOICE SEEDS FOR ALL! Try Them!** For only 15 cents, or five 3c. postage stamps, I will send to any address five packets Choice Seeds: *Pansy, Bouquet Aster, Double Portulaca, Sweet Alyssum, Japan Pinks*, mixed colors of each, and my Illustrated Seed Catalogue for 1880; or above and 4 other choice sorts for 25c. L. W. GOODELL, Amherst, Mass.

**Strawberry Plants** Either kind postpaid for \$1.00. 50 Sharpless 25 Hartstine (Red) 50 Cumberd'l Triumph 50 Brandywine (Red) 100 Crescent Seeding 50 Monarch of West 100 Boyden's Thirty 100 Chas. Downings. Descriptive Catalogue free. 15 Concord 35 Kitchinny 12 Hartford Prolific 35 Dorchester 8 Martha (White) The Lilliar Nursery. 35 Lawsons.

**200,000 WILSON'S ALBANY & CRESCENT** Seedling Strawberry Plants, and 30,000 Doolittle Raspberry, all at specially low rates. Also other Small Fruit Plants and Ornamental Stock low. WM. F. BASSETT, Bellevue Avenue Nurseries, Hammononton, N. J.

## Large Red Onion Seed,

New crop, of extra quality; by mail post-paid, \$2.15 lb.; 1/4 lb. 60c.; less amount, 15c. oz. Circular free. Address **R. W. WOODVILLE, Seed Grower, Northfield, Minn.**

**FLOWER SEEDS. FLOWER SEEDS. 32 KINDS FOR \$1.00.** Having over 40 years' experience in cultivating Flower Seeds, etc., I have made a selection of all the most desirable flowers for general cultivation. Any one selecting from it can obtain just as fine flowers as if selecting from an expensive fancy catalogue, at less than half the expense—as many on the list are sold by others at 10c., 15c., 20c., and 25c. per pkg. The list will be sent to all who apply for it. G. K. GARRETTSON, Flushing, L. I., N. Y. Wholesale and retail dealer in all kinds of seeds.

## P. E. Island Early Rose.

### BEST IN THE WORLD

For early planting and heavy crop. Only \$2.50 per barrel. Stock is limited. Please order early. T. C. DAVENPORT, 124 Dock St., Philadelphia, Pa.

## JOHN SAUL'S

### Catalogue of New, Rare and Beautiful Plants

will be ready Feb. 1st, with a colored plate.—It is full in really good and beautiful plants.—New Dracenas, New Crotons, New Pelargoniums, New Roses; Geraniums, Clematises, &c., with a rich collection of Fine Foliage and other Greenhouse and Hot-house plants, well grown and at low prices; Free to all my customers, to others 10 cts., or a plain copy free. Catalogue of Seeds and Roses free.

JOHN SAUL, Washington, D. C.

## Hardy Perennial Plants.

For descriptions of Alpine and Hardy Herbaceous Plants, the new and rare, as well as the old and reliable, with full directions for propagation and culture, see the Catalogue of

### WOOLSON & CO.

The following are mentioned as either quite new and rare, or of such excellence that they should be better known: Clematis coccinea (Scarlet Clematis); Diceria eximia (Plumy Bleeding Heart); Dictamnus Fraxinella (Fraxinella); Gentiana acaulis (Stemless Gentian); Iberis Gibraltarica (Gibraltar Candy-tuft); Iris Kempter (Japan Iris); Lythrum alatum (Winged Loose-strife); Eriola tenuifolia fl. pl. (Double Slender-Leaved Peony); Spiraea palmata (Palmette Spiraea). A large collection of the best.

### LILIES, PHLOXES AND IRISES.

A fine selection of

## HARDY CLIMBERS, FLOWERING SHRUBS AND FERNS.

The growing of choice Native Plants from distant parts of the country a specialty. The largest stock of Native Bulbs in the country. All the novelties in hardy plants that appear in Europe imported and their adaptability to our climate tested, before placing them in our Catalogue. Great care is taken to have every plant true to name.

### Catalogue of 80 Pages

mailed to any address on application to

**WOOLSON & CO., Box 180, Passaic, N. J.**

**Elegant German Accordion.** Book of Instruction, 200 Pieces Music. \$2.25, post paid, well worth \$4.

**German Concert Flute.** A splendid instrument. Book of Instruction, with 500 Pieces Choice Music. By mail, \$1.75; well worth \$3.00.

**Earlebach Celebrated Harmonica.** Produces sweetest music, easy to learn, everybody is charmed with it. By mail, postpaid, \$1.50.

**Cuveni Cuitar,** fixtures complete. Book of Instruction, with 200 Pieces Choice Music. By express for \$4; well worth \$7.50.

**Earlebach \$10 Banjo.** The most elegant and finest-toned banjo in the world. The body is magnificently painted and burnished with Gilt Silver. The neck is walnut, and beautifully inlaid. Former price, \$10; by express, with Book of Instruction, with 200 Pieces Choice Music, for only \$5.

**"ACME"****PULVERIZING HARROW, CLOD CRUSHER & LEVELER.**

Has twelve **STEEL** Coulter Teeth and ten **STEEL** Cutting Spurs. Cuts over six feet wide and two to four inches deep. The only implement combining Pulverizer, Crusher, and Leveler; performs all three operations at one time in the most perfect manner. Works perfectly on light soil, but is especially adapted to sod and hard clay where other Harrows utterly fail. Agents wanted. Send for circular.

**NASH & BRO.,**

Harrisburg, Pa., and 22 College Place, New York.

**WELL BORING,**

**ARTESIAN WELL DRILLING & MINERAL PROSPECTING MACHINERY.** and how to use, is fully illustrated, explained and highly recommended by the "American Agriculturist" in the November Number 1879. Page 465. Send for Circular, low priced, worked by man, horse or steam power. Needed by farmers in every county. Good business for Winter or Summer, and very profitable. Can get good wells in earth or rock anywhere. We want the names of men that need wells. Send for illustrated price-list and terms to Agents. Address, **Fierce Well Excavator Co., 29 Rose Street, New York, U. S. A.**

**MILL MANUFACTORY**

ESTABLISHED 1851.

**Grist Mills of French Buhr Stone.**

Portable Mills for Farmers, Saw Mills, etc. **18 Sizes and Styles. Over 2,000 in use.** \$30 and upwards. Complete Mill and Sheller \$35. A boy can grind and keep in order. Adapted to any kind of suitable power. Complete Flouring and Corn Mill. **ALL SIZES.** Send for Circular No. 28. **NORDYKE & MARMON CO., Indianapolis, Ind.**

**BURR MILLS.**

**EVERY FARMER HIS OWN MILLER.**

Why buy and use iron grinding mills when you can obtain a first-class French Burr Mill for about same price, doing finest work for family use, and course as desired, and more of it, lasting a generation. Address

**C. C. PHILLIPS, 4048 Girard Av., Philadelphia, Pa.**

**I. X. L. FEED MILL**

All Iron but the Hopper. Cheap, Effective, and Durable. CAN BE RUN BY ANY POWER.

Capacity from 6 to 30 bushels per hour, according to size. Send for Catalogue and prices.

**What Farmers Want.**

They want Pure Ground Bone! Why—because it contains those elements taken from the soil in the grain and carried away, thus impoverishing the land. Pure Premium Bone, made of dry, hard, unsteamed bones, supplies just this waste, as every farmer can learn by practical experience at a trifling cost. Send for a full explanation of how it works.

**Excelsior Fertilizer Co.,**

**Salem, Ohio.**

**IMPROVED FOR 1880.****New Massillon Thresher.**

Read the following Genuine Endorsements:

From **ISAAC JONES, VAIL, Iowa.** The No. 7 New Massillon Separator which we bought of you this season, has given good satisfaction in every respect. There is no machine in this section that will clean grain with it. Its capacity for threshing is equal to anything in the market. Wherever I have done work with it this year I can get the threshing for another season, and I am constantly having farmers who had other machines thresh for them this year and have seen mine work, come and engage me to do their threshing next season. On Flax I must say it does fine work, and is making a name for itself in that, as in all other kinds of grain. I take great pleasure in recommending the New Massillon, and can refer with pleasure to any of the farmers for whom I have done work. My earnings for the season were over \$1,000.

**VAIL, Iowa, Dec. 5th, 1879.**—We cheerfully certify that the work done in this vicinity by the New Massillon Threshing Machine under the direction of Mr. Isaac Jones, is superior to that of any other machine. The grain so threshed is easily distinguished, is cleaner, and in every way more desirable in the market, than that bought from any other machine. Signed **David Evans, Buyer,** and **T. J. Huffman, Receiver of Grain for J. P. Fitch.**

From **JACOB HEPNER, PILLOW, DAUPHIN Co., PA.** I had concluded not to have my threshing done any more with Vibrators, because those that I have had did poor work all over, but while I was attending one of our County Fairs I witnessed a contest between the New Massillon No. 7, with 10-Horse Traction Engine and several other Separators, after which I was compelled to give in, and have my threshing done with the New Massillon and 10-Horse Traction Engine. I examined everything throughout, and found to my satisfaction that there was no grain carried out with the chaff or straw. There was no grain broken, and all was cleaned perfectly clean. After my threshing was done, I was still better pleased to find that a lot of long damp straw which I had, went through without clogging or choking the machine in the least, and much faster, too, than I ever imagined it could. The Shaker and Wind Mill are so well adapted that it don't matter much as to the condition of the grain. People here recommend it as the best machine in existence, and I say it is better. It cannot be excelled.

From **ASA C. NELSON, OWINGSVILLE, Md.** I want to say of your No. 7 New Massillon Separator and 8-Horse Portable Engine, which I bought of your agent, S. L. Kaufman, Gap, Pa., that they stand at the head, in other words, take the front, whilst other machines are going back. They have given entire satisfaction, not only to myself, but to all the farmers for whom I have threshed. I want to call attention to one particular point in this machine, and that is, no matter how fast it is fed, it will not waste the grain. It will separate it wet or dry. I went into Howard County, Md., with it, and there everybody that heard of me wanted me to do their threshing; had I had a few more machines like it, I would have swept the country. I threshed, separated, and cleaned oats so wet that that they looked almost like manure. One day an old darkey came around to take a view of it, and he declared he had never seen anything run so smooth and steady in his life. I want no better Engine; no trouble to run it, and I believe it takes less fuel and water than some other engines that I know. Hear what a farmer says of it: "My threshing did not cost me a cent, because all the grain is separated from the straw."—In conclusion, I would say to any one wishing to get a new outfit, to buy the New Massillon and the Russell & Co. Portable Engine.

### BUY THE BEST.

#### Myers' Improved Wind Mill

The Mill has a solid wheel built expressly to stand any storm, and when in motion moves as regular as a steam engine. Perfectly balanced on the derrick in or out of gear. Pronounced by the best mechanics to be superior to all other Mills. No farmer, stock-raiser, or dairyman should be without one for pumping water for stock, grinding feed of all kinds, churning, and many other purposes. Send for a full descriptive circular.

SILVER & DEMING Manufg Co., Salem, Ohio.

### THE CHAMPION

Is the Best Wind-Power in the Market.

Is perfectly self-regulating, runs no faster in a gale than in a light wind, is very powerful, and never blows away like the tower stands. The Bryden Concave Steel Calk Horse Shoe. The most complete shoe made, with welded steel toe calk, and iron heel calks, hammered, not rolled, and equal in wear to hand-made work. This Shoe is easily fitted, hot or cold, has a perfectly level foot bearing, is light and durable, with a low crease to protect the nails from working loose. The cheapest and best Shoe for Horse Railroads, Carriage and Farm Horses, now made. Made in sizes 1 to 5, hind and forward. Send for circulars. **THE BRYDEN HORSE SHOE CO., 32 Broadway, N. Y.**

View of a heel calk from a Steel Center, Self-Sharpening Shoe, after being worn all winter.  
**PATENT STEEL CENTER, SELF-SHARPENING HORSE AND MULE SHOES.**

A sample set will be sent to any address, except in the States of Minnesota and Wisconsin, on receipt of one dollar. Prices by keg on application.

### THE ADVANTAGE

of the Steel Center Self-Sharpening Shoe is that the calks are always sharp. A thin plate of steel is rolled inside of the soft iron bar from which the shoe is made. The soft iron in the calk partially wears away, leaving the sharp steel center, as shown in the cut. Address **SHOENBERGER & CO., Pittsburgh, Pa.** Agents for the United States except the States of Minnesota and Wisconsin.

### "THE JOHN D. BILLINGS Patent Steel and Iron Horse-Shoe."

Made complete, with Level Spring Platform—Continuous Calk. The best for Horse Railroads, Farm and Carriage Horses in the world. Cures Tender and Contracted Feet, Corns, Interfering, Quarter-crack Lameness, and all evils resulting from the use of the common shoe. Trial Set, with Nails, \$1.00. To measure, place foot on paper, and draw pencil around. Shoes put on cold. No heating of foot. Send for free Illustrated Pamphlet. **THE JOHN D. BILLINGS PATENT HORSE-SHOE COMPANY, 161 and 163 Bank Street, New York.**

### Patent Concave Ox-Shoes.

The only forged ox-shoe made with concavity to fit hoof, and the best and cheapest.

**GREENFIELD TOOL CO., Greenfield, Mass.**

## BUCHAN'S CARBOLIC Medicinal Soap.

The Healing, Purifying, and Disinfecting properties of Carbolic Acid are among the most wonderful facts disclosed by modern science. The best, safest, and most convenient method of using this wonderful Curative is in the form of Soaps.

This Soap is highly prized by physicians and nurses for the sick-room. It purifies and disinfects all unpleasant and dangerous odors, prevents the spread of contagion, and is invaluable in curing sores, eruptions, and all cutaneous diseases.

**Buchan's Carbolic Medicinal Soap is for sale at all Druggists.**

WHOLESALE DEPOT,

**KIDDER & LAIRD, 83 John St., New York.**

**RIVERSIDE FARM.**—Jerseys, Berkshires, and Cotswolds imported, bred, and for sale. Bronze Turkeys, Pekin Ducks, and Light Brahmas. Send for catalogue.  
**C. P. MATTOCKS, Portland, Me.**

**UNRIVALLED.**  
 Circulars free. Catalogues, 10 cents. Scientific Manual, 6th Ed., 75 cents. Splendid Outfits at Bottom Prices.

"A Climate of the Mountains with a Soil of the Valleys."

## The St. Paul & Sioux City Railroad

Traverses the wheat garden and Indian corn region of the Northwest, Southwestern Minnesota and Northwestern Iowa. Not so far North as to be limited in variety of production. Not so far South as to be subject to malaria. 1,000,000 acres of unequalled farming and stock-raising lands with unsurpassed natural advantages for location, climate, soil, and nearness to market. They produce 20 to 40 bushels of wheat, 46 to 60 bushels of Indian corn; 250 to 300 bushels of potatoes; 175 to 200 gallons Amber Cane syrup to the acre. Natural blue joint meadow grass. Undulating prairie of deep rich loam. 1,000 to 1,200 feet above sea level. Lakes and streams, numerous churches, schools, mills, and thrifty villages.

Choice lands on long credit or large discount for cash. For full particulars, address

**JAMES H. DRAKE,**

Land Commissioner, St. Paul Minn.

## THE AMERICAN SUBMERGED PUMP

IS A DOUBLE-ACTING, NON-FREEZING

**WE HAVE NEVER BEFORE**  
manufactured such a variety of Garden Plows, Wheel Hoes, and Seed Sowers,  
**WE HAVE NEVER BEFORE**  
offered Tools so well made, beautifully finished, and so perfect in practice.  
**WE HAVE NEVER BEFORE**  
combined so well, variety of work with perfection and ease of operation. These  
machines quickly save first cost. They are prominent *Agriculturist* Premiums,  
and Jas. Vick says he has never sold any so popular. Correspondence is particularly  
solicited, and descriptive catalogues with numerous engravings are sent FREE.  
**S. L. ALLEN & CO.,** 223 Market St., Phila., Pa., Mfrs of Planet Jr. goods.

## CHEESE AND BUTTER MAKERS' SUPPLIES And Complete MANUFACTURING OUTFITS,

Furnished by **WHITMAN & BURRELL, Little Falls, N. Y.**

Greater number Cash Premiums, First Prizes, and Diplomas received at the recent International Dairy Fair, New York, than by any other person or firm, which included Creamery Apparatus and Cheese Apparatus, consisting of New Economizer Boiler and Engine, Cheese Vats, with covers, Refrigerator Vats for raising Cream, Gang Presses, Knife Curd Mill, Churn, Butter Worker, Curd Knife, etc., etc.

We are sole manufacturers of **GANG CHEESE PRESSES** and **HOOPS** that have the right to use all patents. All royalties are paid by us.

**ECONOMIZER BOILERS**—with and without Engines—both portable and stationary, will make more steam from less fuel than any other Horizontal Boiler built.

Our Patent Knife Curd Mill is recommended by the best Cheese Makers in the land.

We are sole agents in America for Hansen's Danish Preparations. Over 10,000 gallons Hansen's Rennet Extract sold last season. **Liquid Cheese Coloring.** Butter Color prepared in Vegetable Oil by skilled Chemists. Sample free.

We are first hands for Annattoine, Rennets, Bandage, Annatto, Scale Boards, Fairbanks' Scales, etc.

LAPHAM'S PATENT SEAMLESS CHEESE BANDAGE taking EXPENSIVE—NO WASTE—saves trouble and time making up

wonderfully—bound to supersede all other bandage. LESS the bandage. Seven sizes made for 13-inch to 16-inch cheese. Samples by mail.

All correspondence answered promptly. Circulars and prices furnished freely.

**WHITMAN & BURRELL, Little Falls, N. Y.**

## THE BAKER GUNS.

Three-Barrel Two Shot and  
GUN. One Rifle.

We make the best double gun in the world for the money—choke-bore, rebounding locks, extension rib, our \$40 gun has the best English twist barrels, and the best material throughout. All guns sent on trial and guaranteed.

Price—Best English Twist Barrels, \$40. Damascus steel, \$55 to \$70. Send stamp for Descriptive Circular.

A new feature in the Gun line. It is light, compact; from 8 to 10 lbs. in weight. The Rifle is perfectly accurate. It has proved a great success for all kinds of shooting. All guns shipped on trial and guaranteed. Price \$35 to \$50.

**W. H. BAKER & CO., Syracuse, N. Y.**

## NATIONAL WIRE MATTRESS.

NO SAGGING OR ROLLING TO THE CENTER ON THIS BED.

This is the very best and most durable Spring Bed that money can buy. It never can sag, it will never rust in any climate; it can be taken apart and folded up to occupy but little space, and it is the only one getting its elasticity from wire-tempered Springs.

Delivered to any R. R. Station in the U. S. or Canada, free of charge, on receipt of \$10.00.

Address **NATIONAL WIRE MATTRESS CO., New Britain, Conn.**

## Soluble Pacific Guano.

Having taken the General Selling Agency of above Guano, the value of which has already been demonstrated on crops of cotton, corn, tobacco, sugar cane, wheat, roots, and garden vegetables—the Company's sales having exceeded the enormous aggregate of 40,000 tons in a single season—we now offer the same for sale with entire confidence as to its merits. No fertilizer ever introduced in this country has undergone severer tests, or come out of them with its character as a first-class, reliable fertilizer more thoroughly established. In consequence of the satisfactory results of these very complete tests, this Guano has acquired a reputation equal to that formerly enjoyed by Peruvian Guano. It is rich in **Bone Phosphate of Lime**, finely ground (a large proportion of which is immediately soluble), **Ammonia**, and **Potash**, besides other ingredients valuable as plant-food. Soluble Pacific Guano is manufactured at the Company's Works, Woods Holl, Mass., and Charleston, S. C., under the supervision of competent chemists, and none offered for sale is genuine unless having the Company's brand, and the names of John S. Rees & Co., Baltimore, or of the undersigned, branded on each sack. This Guano is offered for sale by our Agents throughout the United States For further information address

**GLIDDEN & CURTIS,**

General Selling Agents,  
BOSTON, MASS.

## Agricultural

Insurance Company, of Watertown, N. Y.

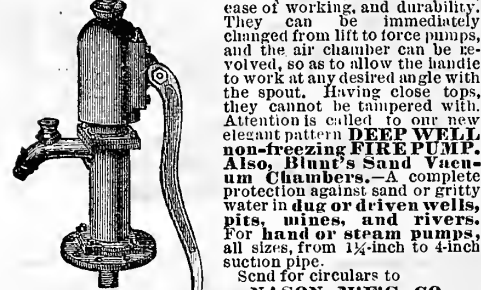

Capital \$200,000.00. Net Surplus, \$216,645.62. Total assets for the security of Policy-holders, January 1st, 1879, \$1,150,068.99. Insures only Farm Property and Residences against fire and lightning. Takes no business risks.

## W. S. BLUNT'S Universal Force Pumps.

Secured by letters patent.

THESE PUMPS HAVE RECEIVED THE "MEDAL OF SUPERIORITY," The highest award of the American Institute for 1878 over all competitors.

These pumps have enormous power, and are for the house or for out-door wells of any depth. They are constructed with special regard to strength, ease of working, and durability.

They can be immediately changed from lift to force pumps, and the air chamber can be removed, so as to allow the handle to work at any desired angle with the spout. Having close tops, they cannot be tampered with. Attention is called to our new elegant pattern **DEEP WELL non-freezing FIRE PUMP.** Also, Blunt's Sand Vacuum Chambers.—A complete protection against sand or gritty water in dug or driven wells, pits, mines, and rivers.

For hand or steam pumps, all sizes, from 1½-inch to 4-inch suction pipe. Send for circulars to **NASON MFG CO., 71 Fulton and 71 Beekman St. New York.**

New England Agency, **A. M. MORTON & CO., 25 Washington St., Boston, Mass.**

Pacific Coast Agency, **Dunham, Carrigan & Co., San Francisco, Cal.**

**RIDGE'S FOOD for INFANTS AND INVALIDS**

Children often need simple nourishment rather than medicine, and how to afford this when the child has little power to assimilate is fully met in Ridge's Food.

## AMERICAN VEGETABLE FIBRE CO.

### FLAX & HEMP RESTORED TO AMERICA!

Great Impediment Removed from Flax and Hemp in the United States. By the Machine of the American Vegetable Fibre Co. Each of the Awards above named was accompanied by the warmest approval of the Judges examining the invention. The speed of its action, and the completeness of its work, surprises all witnesses. The dependence on coarse hand labor, which destroyed our trade for nearly 50 years, is now removed by the substitution of this most ingenious Machine, which will fill the dreary gap between the cultivation and manufacture of these and similar Fibres, and thus restore to us the long lost "Golden Fleece." Illustrated Pamphlets, giving full particulars sent by mail on application to **American Vegetable Fibre Co.**

**JOS. F. DUNTON, Manager,**  
213 South Front St., Phila., Pa.

## COLUMBIA BICYCLE.

A practical roadster, easily mastered, a good Bicyclist can make 100 miles a day over common road; an ordinary rider can make 50 miles per day. Endorsed by the medical profession as the most healthful of out-door sports. Send Set. stamp for price list and 24-page Illustrated Catalogue, or 10 cts. for copy of the Bicycling World, Catalogue and Price List.

**THE POPE MFG CO.,**  
101 Summer St.,  
Boston, Mass.

## THE FERGUSON Bureau Creamery.

CORRECT IN PRINCIPLE. PERFECT IN OPERATION. Awarded the International Diploma at the Dairy Fair, 1879.

It maintains a perfectly uniform temperature at 60°.

It increases the production of Butter fully ten per cent.

It makes Butter unexcelled in texture, flavor and keeping qualities.

It requires the least labor of any system.

It will last twice as long as any other apparatus.

It is a perfect Refrigerator for Cream and Butter.

It can be used with either ice or water

Send for large circulars giving full particulars and many other testimonials.

## Veterinary Cosmoline

Is a heavy oleaginous hydro carbon of the consistency of an ointment, derived exclusively from petroleum. It is absolutely free from acids, alkalis, or moisture. When applied to wounded and inflamed flesh, it is a perfect protection against atmospheric action, flies, insects, animalcules, preventing the generation of microscopic organisms, and allowing nature absolute freedom to heal itself rapidly by a healthy granulation without scars. Never has there been a veterinary ointment that would heal so rapidly all the wounds, sores, and surface diseases of horses, cows, sheep, poultry, etc. For sale by Druggists. Price 75c. in lb. cans. Descriptive circulars mailed in answer to postal cards. E. F. BOUGHTON & CO.,  
211 South Front Street, Philadelphia, Pa.

## AN ELEGANT IMPORTED OLE BULL VIOLIN

ONLY \$3.50

With Violin Box, Bow, Ebony Keys and Italian Strings.

Is celebrated for their rare combination of mathematical and acoustic properties, as the minutest gradation of tone can be produced; hence the brilliancy of tone for which they are noted. On the receipt of only \$3.50, we will send to any reader of this paper one of these Violins, warranted a genuine Ole Bull. Packed carefully in a nice Violin box, with bow, &c. all in the most complete order; and for ONLY 50 CENTS EXTRA, will send a Complete Teacher for the Violin, with 600 PIECES OF CHOICE SELECTED MUSIC, including 21 Brilliant selections from H. M. S. Pinafore. This opportunity to get an Elegant Ole Bull Violin, with box and bow for less than it cost to make the Violin alone, will never offer again; it is the GREATEST BARGAIN EVER KNOWN. To every one sending cash with order we give in place of the regular bow one with a BEAUTIFUL WHITE IVORY FROG. This bow is one of the handsomest we have in stock, of extra length, and retails for \$1.50. In fact no expense has been spared on this Magnificent Offer. Orders invariably filled the day received, and satisfaction guaranteed.

Address Charles W. Story, 26 Central Street, Boston, Mass.

VOLUME XXXIX.—No. 3.

NEW YORK, MARCH, 1880.

NEW SERIES—No. 398.

THE RINGED PHEASANT (*Phasianus torquatus*).—DRAWN BY EDWIN FORBES.—Engraved for the American Agriculturist.

The strict preservation of game in England has its advantages, though a large share of the people think it a hardship. Still only in that, and other countries, where every one can not go about shooting everything that flies, is it possible to have such birds as are shown in the engraving—not only have them, but in great abundance. The Pheasant occupies a place midway between poultry and game. It can only be domesticated with considerable difficulty, and even when confined in an aviary, will destroy its beauty in its efforts to escape; yet it is kept in its present plenty by the aid of the poultry keeper, great numbers of pheasant's eggs being annually hatched by common hens, and the young, when large enough, allowed to run wild. Though we speak of the *English* Pheasant, the bird is not a native of England, but comes from the ancient Asiatic province of Colchis, now known as Caucasus, having been brought to England so long ago

that the tradition is lost. Besides the common Pheasant, with its rich colors of brown, green, purple, and blue, there is the Ringed Pheasant from India and China, and chiefly distinguished from the other by a white ring that almost completely encircles the neck. This species is now almost as abundant in the English game preserves as the common one. Besides these two, there is the Bohemian Pheasant, of a silver-gray color throughout. These three species of Pheasant make up the immense flocks which stock the coverts on the large estates, and of which thousands are killed at the annual *battue*. We read accounts of the participation of royal personages and noblemen in pheasant shooting, and those who do not know, may think it very noble sport for these great people to be engaged in, while in reality they deserve no more credit than if they should go into a barn-yard and shoot at the chickens. Those who are to shoot are given favor-

able places, where they may sit if they please, while the game-keepers with dogs and much noise drive up the birds to be shot, and the slaughter goes on until the shooters—we can not regard them as sportsmen—are tired. Those who engage in such shooting, in which half-tame birds are knocked over, without a chance for their lives, apologize for its cruelty, by asserting that it is necessary for the good of the birds themselves. But for this, the natural increase would be so great that the birds would suffer by starvation, as the land would not naturally produce sufficient food for the immense numbers. Even now, large plantations of berry-bearing shrubs are made to support them. The Golden Pheasant of China is one of the most gorgeously-colored of birds, no description can give any idea of the richness of its plumage. It is said that the experiments made in the naturalization of this in England promise success.

## AMERICAN AGRICULTURIST.

NEW YORK, MARCH, 1880.

## Hints for the Work of the Month.

[The Hints and Suggestions in these columns are never copied from previous years, but are freshly prepared for every month, from the latest experience and observations, by practical men in each department.]

**Spring Work.**—The spring of the Almanac now begins; but the spring-like weather during a large portion of this winter, has allowed the spring work of the Middle, Southern, and Western States, to be greatly forwarded. For the first time in many years, the writer has been plowing through nearly the whole of January, and hundreds of other farmers have done the same. Fencing, ditching, clearing wood-land, and even sowing grass-seed, has been extensively done, as though spring had already come. Sometimes, "the most haste is the worst speed," and it remains to be seen, if, after all, the season's work will be benefited. It is a peculiar time, in which caution should be exercised, lest work done too soon, may need to be done over again.

**Spring Wheat.**—Spasmodic efforts are made now and then, to grow spring wheat in localities where fall wheat only should be sown. Spring wheat requires a cool climate, and the hot and early summers of the Middle States, are not favorable to it. Nevertheless, many farmers have "tried once more," and have failed, as might have been expected, and as we have often given warning would be the result of attempts to grow this class of wheat too far South. Southern New York, New Jersey, and Pennsylvania, are out of the spring wheat latitude, and a line west from Central New York, will as nearly as possible separate the fall wheat and spring wheat districts. Where spring wheat is sown, the seed should be in the ground as early as the soil can be fitted for it.

**Oats** follow spring wheat, being somewhat less hardy. It is thought by some, that oats will take no harm from careless seeding. But this is a mistake, for a good crop, deep covering in a well prepared soil is needed; shallow sown seed does not tiller; while that sown deep will tiller about as much as wheat; with good covering, the seed may be sown much earlier, and will be safe against changes of the weather, while seed near or on the surface, will be destroyed either by frost, or by dry weather, as soon as it sprouts.

**Covering Seed.**—Experience will satisfy any one, that drill-seeding is far better than broadcast sowing; there is a saving of seed, every good seed grows, and none is wasted, and the plants having a better root, are harder and more vigorous. But a drill costs a largesum, is used but twice a year, and for a short time, and for a single purpose only. An implement that will serve more than one purpose is economical. For instance the Aeme Pulverizer, described on page 96, not only breaks up, mellow, and levels the ground, but it covers seed as well, and evenly, as a drill, leaving similar ridges and furrows. With such a machine, all the work subsequent to the plowing, may be done, and well done; for, by a little ingenuity, a broadcast sower may be attached to it. Inventors will, no doubt, in time furnish us with a machine that will plow several furrows, mellow the ground, and sow and cover the seed, at one operation.

**Fertilizers for Spring Crops.**—Top-dressing fall-sown crops, should be done this month if at all. The returning warmth first affects the roots, and they start to grow before the leaves. The stimulant is thus needed for the roots, before the upper portion has appeared to grow. A dressing of 150 or 200 pounds per acre, of any good artificial fertilizer, can be used with profit on any crop, if applied at the proper time, when the growth begins to start.

The present Necessity of American agriculture, is larger crops at the same cost, or a less proportionate cost, than our present small ones. This result can only be secured by additional fertilizing. The present average of our crops is not more than one-fourth of that which the soil is capable of producing, and this extra three-fourths may be produced without any more labor by the use of fertilizers or additional manures; but fertilizers chiefly.

**Artificial Fertilizers** add to the soil certain elements in a condition in which they are immediately active, and force a strong, vigorous, early growth, and so enable the plants to push out a large number of feeding roots, which find out, and appropriate the manure later, when it is in the best condition for plant food.

**A Strong Plant Digests its Food** better than a weak one, and its appetite, so to speak, is more vigorous, precisely as is that of a strong, healthy young animal. It is with the plant as with the animal; early feeding, and vigor of growth, bring early and vigorous maturity. The farmer should study to get early a strong and healthy growth.

**There is no Fear of a Surplus.**—The world's markets are at our feet. The fear that we may produce more than can be disposed of, is a bug-bear and a phantom. It has been conclusively shown, that at a certain price, we can control all the European markets, and that this price, while it pays us fairly, is too small for a profit to the European farmers, who have to pay large rents, heavy taxes, employ expensive labor, and use costly fertilizers.

**Think for a Moment!**—There are seven millions of soldiers in Europe, who are non-producers, and expensive consumers; two or three millions of army horses, all eating, and not working; emperors, kings, princes, and titled persons of all kinds, who are supported in the greatest luxury out of the public revenues; and "the farmer pays for all."

**We Need not Fear to Compete** with farmers so burdened; our prosperity consists in lessening the cost of our produce, and selling it to those nations, who thus hamper themselves with burdens too grievous to be borne; becoming in fact, the food producers for a large portion of the population of the world, nearly one-half living without labor.

**All that is Necessary** is to study and learn accurately the true principles of our profession as farmers, and put in practice the most effective work. How to do these, is what the American Agriculturist has taught, and is still teaching.

**Fodder Crops.**—It has been proved repeatedly, that one acre of good green fodder will feed two cows through the summer. Fodder crops must be put in early. A mixture of oats and peas is the best crop for early cutting, to come in after the first clover, which follows the rye. The two sown together, will yield, on one acre, about as much as if sown separately on two acres. This may be doubted,

**Chicken Cholera.**—"J. R. S., Buffalo, N. Y.," who makes a specialty of Plymouth Rock chickens and Bronze Turkeys, writes: "The cholera has been in the neighborhood for the last three or four months, and some six weeks ago I discovered it in my flock of Plymouth Rocks. On its very first showing, I made up a strong ooze or decoction of White Oak bark, by boiling about a peck of the inside bark, cut fine, in water enough to cover it; corn or meal was soaked in this liquid, and fed to the whole flock, both turkeys and chickens, and to both sick and well, twice a day for some four days. The sick recovered in about two days. No more were taken sick, and all are as well as ever. I did not wait for the disease to kill off any, but took it in its first stages.

**Insect Work.**—"D. L. P." sends from Little Rock, Ark., a piece of stem of a pear tree, which has a clear groove all the way around it, cut half way through the wood, as neatly as if it had been put in a lathe and turned. Mr. P. is desirous of knowing what does the work. It is done by an insect called "The Girdler," of which we hope to give an engraving at another time.

but it is true. Tall growing leafy oats, and tall peas, yield the most fodder; the "Black-eye Marrowfat" pea, grown in Canada as a field crop, is the best for our use, the seed being free from weevil. For a second crop, the earliest small "Canada Gray" pea may be sown. The fodder is in the best condition for cutting, when the peas are in full blossom.

*Southern Cow-Peas* will produce good green fodder for late use, but cannot be sown until May, or after corn is planted. Those who wish to sow them, should look for seed, as it is not always to be had.

*Seeds.*—All the seeds that may be required, should be procured at once. There are some kinds of seed that are better to be changed occasionally, oats and potatoes are of this kind, and should be procured from a northern locality, where the oats are hardier, and the potatoes larger and more vigorous.

*Clover and Grass Seed.*—Clover may be sown this month. When the ground is lifted and cracked by a light frost, the seed may be sown with good effect. But the preferable method is, to sow so soon as the soil is dry enough, and then run over the ground with a light smoothing harrow, and spread 150 lbs. of fertilizer immediately. Orchard-Grass is a most valuable kind to sow with clover; it is early and late, and is unsurpassed for cutting for soiling, or for hay. Three bushels of seed per acre, is not too much, as close seeding is needed, to prevent the grass from forming large clumps or stools.

*Grass Lands.*—It is a mistake to suppose that our climate forbids the success of permanent grass for meadows and pastures. If the right kind of land is chosen, low, moist, and full of vegetable matter, and is kept well manured, and occasionally re-seeded, we can have permanent grass as well as other countries. But it is necessary to sow, and encourage a number of kinds of grass, those with creeping roots being preferable, if the quality is good. This subject is worthy of study and experiment.

*Rolling.*—The roller is both a good and a bad implement; good when rightly used, but very bad otherwise. One good use of it is, to run it over meadows early in the spring, to smooth the surface, press in stones and tufts, mole-runs, and other irregularities. Grain fields are also benefited by rolling, which crushes any lumps left after the winter, presses in roots that may have been thrown out, and covers grass seed. Light rollers are the best, if a heavy one is needed, it is always easy to load a light one, but one cannot make a heavy roller light.

*Live Stock.*—It is a critical time with young animals, and sometimes with old ones. Those that have been well kept, will continue to do well, but it is safest to give all young animals, especially calves, a dose or two of physic. The blood becomes affected by the dry feeding, and close herding of the winter, and some laxative is required. Otherwise the danger of febrile diseases, of which Black Quarter (anthrax or carbuncular erysipelas), is the most frequent, will be imminent. Two ounces of Epsom Salts, or half an ounce of Hyposulphite of Soda, given twice, may save a calf. A pint of Linseed Oil, given two or three times to a cow or a horse, will help the digestion, loosen the hide, and facilitate the change of coat, which is accompanied by irritation of the skin, and slight fever.

*Vermin.*—Make a clean sweep of lice, ticks, fleas, and other vermin, as soon as possible. Oil or grease is the best basis for an effective remedy, and Sulphur is perhaps the best thing to add to the oil. One part of Kerosene, added to four parts of Linseed Oil, makes an excellent application, that is not in any manner injurious to the skin. Ticks may be picked from sheep and lambs. They will come out on the fleece on a warm day, and the best instrument with which to kill them, is a pair of sharp pointed scissors. Kill at the same time every round, red egg that may be found.

*Poultry.*—"The early chick gets the early worm," and the sooner begins to feed itself. March pullets are those which fill the egg basket in the winter time. Therefore set all the broody hens for which eggs can be procured as soon as possible, and take great care of the chicks which come in this month. A warm run out of doors may be made under a hot-bed sash, arranged between two coops, and laid on boards set on their edges.

*A Farm Hospital.*—There will often be accidents and sick animals on a farm. The greatest care cannot always insure against accidents. A pen or close stall made in a warm shed or out building, will be found very useful for sick animals, whether a horse, cow, calf, or fowls. It will be useful for a calving cow, or to keep weaning calves in. It should be at least 12 feet square, so as to give sufficient room.

*Work for Stormy Days.*—Stormy days may be made available for putting all the machines in good order, cleaning and oiling them. This may be done profitably twice during the winter, for a machine depreciates more when idle, than when at work. This fact is well known among machinists, but overlooked by farmers, and their machinery is neglected.

*Remember, Lime-Wash* is a valuable purifier for spring use, anywhere; it cleanses and sweetens.

### Notes on Orchard and Garden Work.

Our country is so large that it is not often that remarks about the weather can have a general interest. All along the Atlantic Coast, and extending for a varying breadth inland, is a district in which, up to the first of February, there was practically no winter. The large number of our readers within this district are much interested in the weather question, which also concerns others, especially fruit growers, outside of it. What is to be the result of this unusually warm weather which prevailed for weeks together? In many cases vegetation in fruit trees, shrubs, etc., has been too far excited to sustain a sudden change to real winter weather (and as we write such a change has come) without injury. To what extent next summer's fruit crops are affected by the weather cannot yet be told, and the anxiety of the fruit grower as to his prospects must continue until after blossoming time. There should be no delay in purchasing all needed implements, fertilizers, seeds, etc., and many who are just starting out in garden and orchard work, will ask: "Where shall I buy?" A word just here may save both the questioners, and the Editors of the *American Agriculturist* unnecessary trouble. It is to be remembered that all suspicious business houses, manufacturers, and dealers are excluded from our advertising columns; only those obtaining space of whom we would order goods ourselves if needed. By a careful consultation of these business notices the question "where to buy" may be answered at once. These advertisers are always glad to furnish information, by sending catalogues of their goods, and to reply by letter. In most cases it is better for those desiring to purchase, or to obtain information about implements and other articles, to write directly to the dealers rather than to us. In garden work there are two extremes to be avoided: being always behind the season, and always ahead of it. The soil should not be worked when it is so wet that it is sticky, and will afterwards dry into a hard mass—and on the other hand it should be worked so soon as it is dry enough. Let both the season and the crop go along together to obtain the best results.

### Orchard and Nursery.

In planting an orchard, the ground should first be prepared by thorough plowing and manuring. This matter is often ignored, while the fact is that, except upon new land, unless the soil taken for the orchard is in at least as good condition as would be regarded proper for wheat, corn, or other farm crops, a paying orchard cannot be expected. It would have been better to have prepared the land last fall, but the failure to do so need not prevent one from planting; plant now, manure later. The trees should be ordered at once, as a brief delay, may find the best varieties—just the ones wanted—all exhausted. If the ground is not ready when the trees come, they should be heeled-in, that is, their roots covered with soil, that they may not dry out. In setting the trees, great care should be exercised; it does not pay to hurry through this kind of work. The tops should be cut back, so that the evaporating leaf-surface of the transplanted tree, may correspond pretty nearly with the reduced amount of absorbing root-surface.

*Trimming before Planting.*—This is a matter of much importance, the whole future of the tree depending upon its being properly done. No matter how carefully a tree may be taken up, some of its roots will be injured, and as ordinarily lifted, the trees that come from the nursery do not have half the roots that belong to them. One must exercise judgment in the matter, but it is safe to say, that one-third of the length of shoots should be cut away at any rate, and often more must be removed.

*Laying Out.*—The common method is the Square; but if the most is to be made of the ground, what is called the Quincunx, gives the most available space to the greatest number of trees. For this plan, with illustration for setting, see the *American Agriculturist*, September, 1879. A list of the best kinds of fruits for the orchard, is given in the Notes of the January number for the present year.

*Injured Trees* must be looked to; if broken down, they should be trimmed; girdled trees will need to be banked up with earth, or grafts joining the bark above and below the girdling, should be inserted.

*Pruning* can be continued until the sap starts, covering all large wounds with a grafting wax, made of three parts each of beeswax and rosin, and two parts of tallow, melted and thoroughly mixed. This is to be used in the melted state, applied with a brush. Some prefer to use paint instead.

*Grafting.*—Plum and cherry trees must be grafted earlier than the pear or apple. For directions with illustrations of grafting, see the last month's Notes.

*Cions.*—A good supply of cions should be secured early; they must not be cut after the sap begins to flow, unless to be inserted immediately.

*Budding Stock.*—The twigs and branches above the buds, that "took" last summer, are to be removed, leaving only a half-inch or so above the bud.

### The Fruit Garden.

In selecting a spot for a fruit garden, choose a warm place, and as near the house as possible, that it may be both convenient for gathering, and more secure from trespassers. The soil should be well drained, deep, mellow, and enriched with well rotted manure. The importance of a good selection of varieties cannot be too strongly insisted upon. For a list of the leading kinds of the various fruits see the January number Notes; for others see the Catalogues of dealers. The selecting of new sorts for the main reliance, is not recommended. Let the bulk of the planting be of old, and thoroughly tested varieties, rather than of new and untried kinds.

*Planting.*—So soon as the ground is settled, plant the trees, shrubs, etc., that they may get an early start, and be well established by the time drouths come. Like animals, much depends on early growth.

*Blackberries and Raspberries* start very early, and it is best to set them in the fall; but very early in the spring will answer. The canes produced this year, will bear the fruit the following season.

*Strawberries.*—Old beds are to be uncovered. The method of cultivating the vines in rows three feet apart, is now generally considered the most satisfactory. See article and engraving of the "Sharpless" Strawberry, on page 103 of this number.

*Grapes.*—Every farmer's family should have all the grapes they can eat, from September to January. It is not necessary to have a large vineyard for this; a few vines, each of the best sorts, and properly treated, will give a great amount of fruit. There are hundreds of out-of-the-way places where a vine may be set, such as along a fence, or it may be by the side of a shed or barn; with good soil, and care in pruning, satisfactory returns may be expected.

### Kitchen and Market Garden.

The Notes for this department last month, were unusually long, and much then given is timely now. A careful review of the subject of Hot-Beds will help those who inquire about raising early plants.

*Cold Frame Plants.*—Cabbages, Lettuce, and Cauliflowers, should be set out as soon as the ground can be worked. In market gardens, Lettuce is set between the rows of Cabbage and Cauliflower.

*Hardy Vegetables* are those that may be planted,

or the seed sown, "as early as the ground can be worked." Of such are; Beets, Cabbages, Carrots, Cress, Cauliflower, Celery, Lettuce, Parsley, Parsnip, Onion, Pea, Radish, Turnip, and Spinach. The

*Tender Vegetables*; Beans, Cucumber, Okra, Pumpkin, Squash, Tomato, and Watermelon, should not be sown until the ground is well warmed, or according to the old rule, "about corn planting time,"—a very safe guide in most localities.

*Novelties*.—New varieties are offered every year, and their claims to public favor are presented. It would be a mistake to rely upon novelties for the main crop, which should always be of well established varieties; but we advise those who can do so, to experiment to some extent with novelties as a source of pleasure, and sometimes profit.

*Asparagus*.—The coarser parts of the manure with which the bed was covered last fall, are to be raked off the bed and the fine portions forked in.

*Greens*.—See article on page 104. The remarks on Spinach there given are of special importance.

*What Vegetables Shall we Raise?*—For a number of years we have given a list of the standard varieties of vegetables as a guide to the inexperienced. This year Mr. Henderson gives a list of the old and reliable kinds, together with the results as obtained in his trial grounds, with the recent novelties.

### Flower Garden and Lawn.

For keeping up the freshness and vigor of the lawn, a spring dressing should be given, either of ashes, guano, fine bone, Nitrate of Soda, or a rich and thoroughly fine compost. Sow grass seed on any bare spots. In planting ornamental trees, grouping, rather than formal planting or setting in rows, is to be encouraged, so far as the nature and size of the grounds will permit it to be done.

*New Lawns*.—Let the soil be in a fine state of tillage by thorough working and manuring, after which, for heavy clay soils, Kentucky Blue-Grass is to be sown. Red Top is best for light and sandy soils, with a little mixture of White Clover in both cases. The seed should be applied liberally, as a fine turf can only be had when the plants are crowded. All the way from two to six bushels to the acre are advised. If what we buy were all seed, no doubt the smaller quantity would be enough, but in the uncertain relations between chaff and seed, one can not be sure of properly thick-seeding with less than four bushels. Sow half the seed in one direction, and cross-sow with the other half. The seeding should be done as soon as the land can be put in proper condition.

*Walks and Drives*.—A solid foundation is the only surety for a good walk or drive; and to secure this, use large stones for the bottom, begin below the reach of frost, and smaller ones nearer the surface. A walk or drive that is cheap in the beginning will always be unsatisfactory and dear in the end.

*Annuals*.—Sow these in hot-beds about six weeks before the outside beds are to be ready for them.

*Bulbs* in beds may be uncovered so soon as warm weather sets in, covering again on very cold nights.

*Turfing*.—In selecting turf for use around beds and along walks, etc., see that no unwelcome weeds are thereby introduced. The foundation for the turf should be as carefully prepared, as for seed.

### Greenhouse and Window Plants.

As the days get longer and warmer, the attacks of the insect pest will be more vigorous. It may be necessary to fumigate as often as twice a week, using tobacco stems freely for this purpose. For the Red Spider, thorough washings and use of the syringe are the most effectual remedy.... An abundance of water and air will be required; the sashes and windows may be left open much of the daytime.

*Bulbs* brought into heat will soon start and produce flowers. Those that have bloomed should be allowed to complete the growth of their leaves.

*Propagation* of stock of bedding plants for sale or home use should now be going on.

*Seeds* for plants to go into the open ground are to be sown in boxes and given a plenty of heat.

## Trials of Vegetables in 1879.

BY PETER HENDERSON.

Very few new varieties of vegetables that have come under our notice have shown any special merit during the past year, though the varieties tested in our trial grounds were more numerous than ever before, numbering over 800 different sorts, and embracing nearly every class of vegetables in cultivation, all of each class being grown in the same soil and under the same conditions. The great use of this comparative test of so many different kinds is not so much to know what kinds to grow as to know what not to grow. In vegetables, as in fruits and flowers, we all offer far too many varieties; the public would be far better served if nurserymen, seedsmen, and florists would have the courage to cut out three-fourths of the varieties of fruits, vegetables, and flowers from their lists, describing only a few of the best of each class, and also naming such as proved to be specially unworthy of culture. I give the following brief notes on vegetables as they appeared in our grounds at Jersey City Heights, N. J., during the summer and fall of 1879:

*Asparagus*.—In October, 1878, we planted 12 roots each of Colossal, Giant, and Mr. Smalley's Defiance, but the number was too few to give any certain results. In the fall of 1879 we planted 200 plants of each kind in carefully prepared ground, and will be better able to judge this season which is best for general cultivation. I am inclined to think favorably of the Defiance, but will not hazard an endorsement until our trial is more complete.

*Beans, Bush*.—Flat-podded China proved earliest, Mohawk next; for general crop, Valentine's. The "Golden Wax" is a new and distinct variety that proved on a second year's trial excellent, being early, stringless, and of very fine flavor; it is one of the best shell beans. For *Pole Beans*, nothing is better than Large Lima. Giant Wax is a stringless pole snap bean, but has no special merit.

*Beets*.—The old Bassano is earliest, but on account of its light color, is now superseded by the Egyptian, which is by far the best of the dark colored, round varieties. Bastian's Blood Turnip, a newer kind, is second in earliness to Egyptian. The best long variety was Long Smooth Red.—*Mangels*. Norbitou Giant proved the best red, and Kinver Globe the best of the yellows.

*Cabbages* show no change in the past three years. For earliest, the Wakefield still leads, then comes Early Summer, only about 8 days later, but of nearly double the weight. This sort, we find, is more valued generally than any other early cabbage, as it seems to adapt itself better to all sections of the country. The Wakefield has never been a favorite in the Southern States, though almost exclusively grown by market gardeners at the North, but the Early Summer is an equal favorite, south and north, and is now perhaps most generally cultivated.

*Savoy Cabbages* we find are, as they deserve to be, yearly becoming more extensively cultivated. An improved variety, called Netted Savoy, introduced last season, we find to be one of the best.

*Cauliflower*.—Our reports from the new variety named Early Snowball, fully confirm our own tests. This was first sent out in 1877, and was illustrated in the *American Agriculturist* of Feb., 1878. It undoubtedly is the earliest, largest, and most certain to head of any variety we know. It is this season classed by some seedsmen as synonymous with the Erfurt; this is an error, as it is entirely distinct from and superior to the best strains of Erfurt. All our New Jersey market gardeners now grow it exclusively for early crop. For late crops, which are mainly grown by the Long Island gardeners, the Half Early Paris and Algiers are the best.

*Celery*.—The four best sorts for this section are Golden Dwarf, Half Dwarf, Dwarf Sandringham, and London Red. For market, I should advise the relative proportions of four of Golden Dwarf, three of Half Dwarf, two of Dwarf Sandringham, and one, or one-fourth as much as of the first, of London Red. In my opinion, it is always best to grow several kinds of celery; so much

depends on location and season, that it is not safe to risk a crop of all one kind, as we find that varieties that will "burn" or "scald" in one place, are entirely exempt from it in another. Where the Dwarf Sandringham does well, nothing is so good, as it is always entirely solid.

*Carrot*.—The Danvers was tried more fully the past season, but whether our soil is not adapted to it, or from other causes, our success has not been that claimed for it as giving the heaviest crop of any variety; the Improved Long Orange for general crop proved better. For forcing under glass, nothing surpasses the Scarlet Horn, while for early crop to be bunched and sold while young, Half Long Red or Stump-Rooted is the best.

*Sweet Corn*.—No change from the reports of last year. Crosby's Early stands first as both earliest and sweetest. Narragansett and Minnesota are a little earlier, but not so good. The very general and large demand for the Egyptian, sent out in 1877, tells of the value attached to it; almost all agree that it is the best flavored of all the Sweet Corns; being of very large size, it is one of the latest, but is none the less valuable on that account, as it gives us a supply after the general crop is done with.

*Cucumber*.—The best long, forcing English kinds are Sion House and Telegraph; these fancy sorts are now getting to be much sought after by our first-class hotels and restaurants. Improved White Spine is yet mostly grown both for a main crop under glass and in the open ground. Green Prolific for pickling. The Burr or West India Gherkin is used to some extent as a fancy pickle.

*Egg Plants* show nothing new. New York Improved for general crop, and Long White and Black Pekin for variety.

*Endive*.—Moss Curled is the best for garnishing, and is equally edible with Green Curled and Batavian, the most used market kinds.

*Leeks*.—Carenton, very large and mild flavored, is perhaps best, though the American Flag is yet most used for general crop.

*Lettuce*.—As usual, our trials of this popular vegetable were on a large scale, over 50 kinds being experimented with. A number of "new names" proved to be old and well known sorts, and none among the large number proved to be new, or if any were new they had no merit to entitle them to be retained, so we again name as the best standard sorts: All the Year Round as the best *plain leaved*, Black-Seeded Simpson (new, 1878) as the best curled, and Silesia or White-Seeded Simpson as best curled for general crop. For forcing in frames Boston Market is now almost exclusively used.

*Melons*.—The standard market variety is the Hackensack, so-called from being extensively grown by the market gardeners near the town of that name in N. J., who, by careful selection, have brought this variety of Nutmeg Melon to a high degree of perfection. It is of large size, finely netted, green fleshed, and of excellent flavor. Surprise, a comparatively new sort, with whitish thin rind and salmon-colored flesh, is very rich in flavor, exceedingly productive, and of good size. Cassaba, a long, large kind, with yellow flesh, is also excellent either for market or private use.... *Water Melons*.—Mountain Sweet and Gipsy are the best market sorts. Phinney's Early is perhaps the earliest. The true White-Seeded Ice Cream is also one of the best.

*Okra*.—Improved Dwarf Green.

*Onions*.—Nothing different in Onions to report. Red Globe and Red Wethersfield in reds, White Globe and White Portugal in whites, and of yellows the Yellow Danvers. The varieties best fitted for the South are Queen, Giant Rocca, and Red and White Italian Tripoli, some of which grow very large, and are of mild flavor.

*Parsley*.—Fern-Leaved and Moss Curled.

*Parsnips*.—For general crop, Long Smooth, and for early, Short Round.

*Peas*.—American Wonder proved early and exceedingly prolific, and is without doubt the best of all the dwarf wrinkled peas; quality first-rate. We tested upwards of 20 "new" kinds, all claiming

superior earliness and productiveness; but nothing surpassed the Improved Dan'l O'Rourke for first early, and we therefore still recommend it as the best for general early crop. For second early we name first Alpha, then Fill Basket, Premium Gem, and William I. For late, Champion of England and Omega. Some of the Long Island farmers practice sowing the early varieties as a second crop in August, to be sold in October. For this purpose, Improved Dan'l O'Rourke is perhaps the best. When a good crop is thus raised, it is very profitable; but so much depends on the season that that is not always certain to be obtained.

**Potatoes.**—The St. Patrick has had a general and thorough trial, and not only from our own grounds, but from all sections of the country the reports are almost, without exception, so favorable that there is but little doubt of it becoming a leading sort. R. O. Bunnell, Dunmore, Pa., testifies that from 1 lb. cut into eyes (not from cuttings), and planted May 10th, he dug on Sept. 15th 226 lbs. All testimony goes to prove its wonderful productiveness. It is white, very oblong, and handsome; quality full average.... Beauty of Hebron.—A new early sort, very productive, and of good quality—a variety grown extensively in Northern New York. Genesee County King is late, but of average quality. Early Ohio is also fine and early, and will, we think, become one of our standard sorts. The earliest of all our potatoes was the Alpha, but the yield was poor.

**Peppers or Capsicum.**—Large Bell or Bull Nose, and Sweet Spanish, for general use. Long Cayenne and Cranberry for pickling.

**Radish.**—The best early kinds are Long Scarlet, French Breakfast, and Scarlet Turnip, which are nearly alike in the open ground, but for forcing the new Dark-Red Round and White-Tipped Scarlet are the best, as the tops are small and the root develops rapidly. In summer Radishes the new Olive Shaped Golden Yellow sent out the previous year proved very satisfactory. For winter, the Black and Grey Spanish and Rose China are the best.

**Spinach.**—We have tried over 20 samples of Spinach the past season, and find the Savoy-Leaved the best, especially for market. Our trials also developed the fact that a great deal sold for Savoy-Leaved is only the ordinary Round-Leaved Spinach. The new Thick-Leaved we find to be a very good sort, tender, and of fine quality. Large-Leaved Viroflay is a sort with large foliage; very good. We find great difference in the various stocks of Round-Leaved Spinach, some being quite inferior to others in quality and weight of crop.

**Squash.**—For summer varieties, Summer Crook Neck, and White and Yellow Bush. For winter, Hubbard and Yokohama.

**Turnips.**—For early, White and Red-top Strap-leaf; White Egg is yet rather new, but is fast gaining favor, as it is equally early as the Strap-leaf, it attains a greater size, and is remarkably handsome; it is also an excellent keeper, and can therefore be grown in fall for winter use. For second early, or winter for general crop, Yellow Globe and Golden Ball. French White is the best flavored of the Ruta-baga; the American Improved Ruta-baga is more used, and really one of the best.

**Tomatoes.**—I have repeatedly given my opinion in the columns of the *American Agriculturist*, that we had reached that point in earliness with the Tomato where further progress had stopped. This was very forcibly confirmed last season. There was a great excitement among the market gardeners in the vicinity of Newark, N. J., one of them having about an acre of a "new" Tomato that was ripe 10 days before any other. The owner came to us and offered to dispose of the stock of seed. I took him through our collection, and showed him a variety that had some ripe fruit, and entirely distinct in foliage from any other. He admitted that it was very like his. A visit to his field, and comparison, showed it to be identical; and both were the old Keyes' Prolific, introduced a dozen years ago, and which is, without question, to-day the earliest of any smooth Tomato, but too small and inferior in quality for a general crop. I was never more impressed with the value of our trial ground, for had

we not had this lot of Keyes' Prolific for comparison, the chances were 20 to 1 that this old variety would have again been sent out as a new sort with a new name; the man into whose possession it had come had never heard of Keyes' Prolific, and honestly thought he had a new sort.—We find that the favorite Tomato for general use is Acme, early, smooth, prolific, and solid. The color is of a purplish shade, and for some time this was an objection to its sale in the markets, but its other excellent qualities have offset this, and now it sells equal to anything offered.—Golden Trophy is a very pretty fancy variety, of a rich shade of yellow, is equal in all respects to the original, red Trophy, which is yet a standard sort, though not often seen so smooth as at first. The kinds which appeared to be best for general market purposes with us the past season were as the year before, viz.: Conqueror and Canada Victor, while for canning, Paragon and Hathaway's Excelsior are equally desirable.

### Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the *American Agriculturist*, from our record kept daily during the year, show at a glance the transactions for the month ending Feb. 10th, 1880, and for the corresponding period last year:

Of the notable features of general business, since our last Review, have been the growing ease in Money, which contributed to stimulate operations; very extensive dealings in the Public Funds, as also in miscellaneous Bonds, Mortgages, and Stocks at advancing prices; increasing activity and buoyancy in Real Estate, Dry Goods, Hardware, Metals, Drugs, Dyes, Chemicals, and toward the close in Groceries, with an improved demand also for Boots and Shoes, Fish, Petroleum, Naval Stores, Paints, Tobacco, Rice, Hemp, Oils, and most kinds of building materials.... Hides and Leather weakened perceptibly in price, on a tamer movement.... Hay and Straw met with a fair inquiry and generally strong quotations.... Seeds attracted more attention, and closed more firmly.... Cotton has been freely dealt in, chiefly in the option line, but at variable rates, opening buoyantly but closing in favor of buyers.... A better demand has been reported for Wool, which has been quoted somewhat firmer, leaving off with an upward tendency, in view of comparatively meagre supplies of domestic product available.... Provisions have been quite active, but, in the instance of hog products, fluctuating frequently in value, closing generally lower. Butter also yielded slightly, and Beef declined a trifle. Cheese and Eggs advanced rather sharply.... Breadstuffs have been unusually variable, on freer movements in Wheat, chiefly in the speculative interest, though other articles, in this line, exhibited only a moderate degree of activity. Export purchases of Wheat and Flour continued on a restricted scale, the relatively high prices current here impeding operations. Corn met with a readier market for shipment, and, early in the month, at hardening prices. A good demand was noted for Oats, and a fair inquiry for Rye and Barley; Oats at stronger rates; Rye at irregular figures; while Barley receded, under more liberal and urgent offerings, with a moderate call for export account, mainly for feeding or low grade stock. The visible supplies of Wheat, embracing the hoards at lake ports, in transit, and on the seaboard—at latest dates, embraced about 30,100,000 bushels;—of Corn, 13,100,000 bushels; of Rye, 979,000 bushels; of Barley, 4,155,000 bushels; and of Oats, 3,080,000 bushels, against, on Jan. 17, an aggregate of 31,024,000 bushels Wheat, 11,927,100 bushels Corn, 1,068,100 bushels Rye,

4,403,100 bushels Barley, and 3,318,000 bushels Oats. Receipts at this port have fallen off considerably, due, in good part, to interruptions in the forwarding movement, resulting from speculative manipulation of the markets of the interior, as well as the seaboard. Ocean grain freights further declined to the lowest quotations made here, on actual business contracts, in many years, having been down, by steam to Liverpool, to 2½d. per bushel; to Bristol, by steam, to 3½d. per bushel; to Antwerp, by steam, to 4d. per bushel; and by sail to Cork, for orders, 3s. 9d. @ 4s. per quarter of 480 lbs. Toward the extreme close, a livelier inquiry was developed for Flour and Wheat, especially for shipment, favored by the latest market advices by cable, which were of an encouraging tenor, leading to a rally in prices of Flour, of 10@20c. per bbl., and of Wheat, of 2@3c. per bushel, winding up firmly. Important shipments of Wheat, on through freight account, were reported recently, and represented as, in good part, consignments, receivers and holders availing themselves of the current extremely low rates on ocean freight, in which, however, a slight rise occurred in the final negotiations. Corn fell severely, particularly new crop, under a pressure to realize. Oats also weakened again, and Barley closed barely steady. Rye was advanced sharply, in view of the light offerings, with prime Western and State, boat loads, quoted up to 95c. bid, and as high as \$1 asked, per bushel. Hops left off very tamely, owing, partly, to the very confident views of sellers of the better qualities; very choice to fancy lots of State having been held as high as 38@40c. per lb.

**Beeves.**—The market opened weak in spite of light receipts, but without any decline in prices; an export of 2000 head the first week helping it greatly. In fact, this trade is all that sustains the values of live stock in the United States, for a shipment of 5,770 head in one week—a quantity unprecedented, and showing to what enormous proportions the business has grown—is clearly the mainstay of the trade. This outlet, like a pendulum of a clock, checks irregular movements, and the past month has kept a very steady market. Towards the close, prices gave way a little and sales were free at a small decline. Dressed beef was offered in plenty at 7½c. per lb.; the range for poor stock 55 to 56 lbs. per 100, was 7½ to 8½c. per lb. for fair to prime, 8½c. @ 10c. for 56 lbs. per 100, and extra to dress, 57 lbs. per 100 weight, 11½c. per lb. .... **Cows.**—There has been a quiet sort of demand for good milkers, having been taken at prices somewhat lower for everything but choice family cows. The market closed steady at \$30 to \$50 for fair to good, and \$60 to \$65 for choice.... **Calves.**—Business in veal has been brisk, except for grassers, which have been neglected under a good supply of veals, and brought 2½ to 3½ cents per lb. alive. Veals have sold for 6c. to 8½c. per lb. dressed weight.... **Sheep and Lambs.**—Prices have been well sustained and an active demand has existed during the past five weeks. Lambs ranged from 6½c. @ 7½c. per lb. live weight, and sheep from 5c. to 6½c. per lb.; some choice wethers have sold at \$6.60 per 100 lbs. The closing prices were without change on a firm market.... **Swine.**—A quiet market and steady prices have marked the past five weeks. The business has been done mainly at 5c. @ 5½c. per lb., and at the close, prices were slightly lower, the bulk of the sales being at 5c., and a few at 5½c. per lb.

**The Horse Market.**—Stock has been accumulating for months past with nothing to move it but inquiry. A few good driving animals have changed hands, but for work and common horses trade has been entirely nominal. The outlook seems to foreshadow a late and slow trade for spring with unsatisfactory prices for dealers.

**Pages Worth Studying.**—As always, upon the approach of spring work, there is an increased number of announcements from dealers in Seeds, Plants, Implements, Fertilizers, etc., and in this year of renewed activity in all departments, the crowd is greater than ever. To avoid the least trenching upon our reading columns, four extra pages have been added to accommodate our friends, and still a large number of late comers are necessarily left out. These advertising pages are of great value to our readers as a source of information, and worth studying carefully to learn what is offered, old and new, and by whom. It is equivalent to going to a great Fair, where a multitude of reliable men exhibit what they have to supply. Reading what others say in a business way, and how they say it, will usually give one new thoughts and suggestions useful in his own calling. We have excluded many advertisements because not approved, or because from men not known to be, or not believed to be, every way trustworthy.... When corresponding with any of our advertisers, or sending for catalogues, etc., it is well to state that you are a reader of this Journal. They will know what we expect, and what you expect of them as to prompt and fair treatment.

**Toads** are the friends of gardeners, destroying the injurious insects in large numbers. In the extensive vegetable gardens around London and Paris, the toads are looked after with great care, and are even a part of the stock invested in the business. Many of the toads in and around London are brought from France, where they pay as high as six shillings a dozen for them.

## MARCH ON.

"Forward!...MARCH!" is the general order for THIS month. Not only is it implied in the name of the month itself, but in the Season also. The hibernation, the resting of the winter, is coming to an end. Work in the Fields and in the Gardens will soon begin, where it is not already under way. Much of the success depends upon *planning well*.

Is there a man who cultivates a farm, an orchard, a vegetable or fruit garden, or a flower plot, or who raises animals, that can not find *useful* hints and suggestions in the pages of this Journal? If there is, it is *not* the paper we intend it to be.

But we believe it will surely pay *every one* to study these pages.

Hundreds of thousands are already doing so. What of the hundreds of thousands who do not?

We fully believe they *ought* to do so, for their own good, and if we could see them we would tell them so, and explain *why*.

As we cannot, we ask our readers to do this as a double favor to them and to us.

Last Autumn we prepared the largest and best assortment of Premiums ever offered—valuable articles to be *presented* to those who take the trouble to invite new readers, and receive and forward the names of both old and new subscribers for 1880.

**All those Premiums are still offered to our friends, new and old, and will be offered during March, and until June.**

**March** is a good month to carry on and fill out Premium Lists already in progress, and to start new clubs. Many thousands of such names are sent in *every* March.

We invite all our friends to take hold with fresh energy, and secure some valuable articles from our list. (If any one has not the full Premium List at hand, send at once a postal card request, and it will be forwarded free.)

**IT WILL PAY A HUNDRED FOLD,** to have in *every* neighborhood, at least a few good books on Animals and their Diseases, on General Farming, on Gardening, on Fruits, on Farm Implements, etc., and at least a few Standard Works on other subjects. These books *ought* to be accessible to all for reference in case of need, as well as for reading by all—a sort of circulating or reference library to be in charge of some one.

*Never before was there so good an opportunity as now to get a collection of such Books at very small cost.* Any ten or more persons contributing \$1.50 each, will each be supplied with the *American Agriculturist* for 1880, and **in addition, one Dollar's worth of Books** will be presented for each Contributor to the fund. The books may be selected from the list of **847** Good Works named in our premium sheet. Where the subscriptions are already sent in for 1880, subscriptions for 1881 may be added, when desired, to increase the Library as far as possible. Many new subscribers can also be found. *Every* neighborhood may thus secure such a Library. It only needs some enterprising man, young or old, to take hold of the matter as a leader, and he will soon have plenty of *helping* hands, and heads, and hearts. If the Men neglect it, their "Better-halves," or Daughters, always foremost in good works, should take it up.

**N. B.—Special.—An Answer to many Inquirers:**—While ten subscribers for one year are preferred to one subscription for ten years, yet, when specially desired, any subscriber can pay for as many years in advance as he may desire, and count each year as one subscription in making up the Library Club above described. Thus: \$15 will pay for Ten Years' Subscriptions and Ten Dollars Worth of Books for this spring only.

containing a great variety of items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

**What to Plant in the Garden,** is always a puzzling question, and especially so since the very late increase in varieties. There is a great choice both as to quality and amount of product. Even in a very small garden, a right selection of seeds will make a difference of many dollars of real value in what is grown for one's own use—the labor, expense and care being the same. There is a multitude of new things worth many times as much as the old "standard" sorts, both as to quality and yield. But among the hundreds of varieties of new peas, beans, cabbages, lettuce, corn, potatoes, sweet corn, tomatoes, etc., etc., each strongly praised by some seller of seeds, the layman is sorely at loss to know what to select, and quite likely to get many poor things. To all such, the results of 800 trials given by so careful an experimenter as Peter Henderson, will be of great value. See page 86.

**Nitrate of Soda,** or Chili Saltpetre, is one of the leading mineral fertilizers supplied from the immense deposits in the rainless desert of Southern Peru. Attention was first called to it by Alexander von Humboldt, in the early part of this century, but it is not over fifty years ago that it was first shipped abroad to any extent. The Nitrate of Soda industry is to-day a large and rapidly growing one, there being over 250,000 tons of this fertilizer mined and exported per year, though it is not all used upon the land, a large share going to the manufacturers of chemicals as a source of Nitric Acid. It is a formidable competitor of the celebrated Peruvian Guano.

#### \$298,760,867 for Widows and Orphans.

—In studying the Statement of the Mutual Life Insurance Company, as given on page 117, we were forcibly impressed with one item, the "Policies in force January 1, 1880," amounting to nearly three hundred millions of dollars, insuring this sum to the survivors at death of the holders of 95,423 policies of insurance. As will be seen, over seven million dollars were paid to the survivors or representatives of insurers during 1879, but the receipts were over seventeen millions despite the reduced rates of insurance, and so there is a surplus of over Eleven Millions beyond the amount needed to render safe and secure the policies in this Company.

### The American Agriculturist Fertilizer Experiments.

#### The Farmer's Own Experiments.

The enterprise first proposed and carried out by the *American Agriculturist*, has given results of great value. This plan included showing the farmer how to experiment with fertilizers, and furnishing him at cost, or less, with fertilizers of standard quality for the experiments. Some of the reports of last year's experiments, are given elsewhere by Prof. Atwater. Can any farmer who uses fertilizers at all examine these reports, and not see how valuable the knowledge thus gained must be to the experimenter? Would he not gladly have such a knowledge of the requirements of his own soil, as these farmers have of theirs?

Can there be any stronger evidence as to the folly—the wastefulness, of the promiscuous hit-or-miss use of fertilizers? It is just as important to know what the soil does not need, as it is to know what it does require, and what may be applied to it with profit. This knowledge can only be obtained from the soil, and through the medium of experiments. So well satisfied are we of the utility of the experiments already made, that we propose to continue them the present year. We commend Prof. Atwater's account of last year's experiments to the attention of every farmer. If the reader would have a similar knowledge of his own soil, we can provide him with the means of acquiring it at a very small outlay. The full explanation of the plan will be given next month; it will not, however, be essentially different from that followed last year, and which was described on pages 128-129 in April 1879.

#### The Experiments for 1880.

As some of the details for this year have not been decided upon, a full explanation will not be given until next month. It is not probable that there will be any essential variation from the methods as given in April 1879, and those of our readers at the South, where the season for work is already quite advanced, who wish to consider the matter earlier, may take last year's work as a general guide. The prices of the parcels may, or may not be, slightly advanced, owing to the general higher cost of most materials.

**Off Color.**—At a sale of a superior herd of Jersey cows, a great pecuniary loss was sustained by the owner, because the animals did not have the fancy superficial marks, now made so much of by the ruling spirits of the Jersey Herd Books. Black tongues and black switches are not strictly Jersey marks—many of the best of that breed do not have them. Breeders should remember this, and look to the milking and breeding qualities of a dairy cow, as of the most importance, and banish the expression—"Too much off color to be fashionable."

**Trouble in Churning** is frequently complained of in winter. Much of the trouble is due to a neglect of the temperature which can not be told with any approach to accuracy except by using a thermometer. If the cream is brought into a warm room until the thermometer shows it to stand at 60°, we rarely find any difficulty. In old times the cream was thought to be bewitched, and as the power of a horse-shoe to keep witches away is well known, it was used to drive the witches from the churn. The horse-shoe was heated red hot and dropped into the cream in the churn. It drove the witches away when it brought the cream to the right temperature.

### Sundry Humbugs.

A wonderful change indeed has come over our correspondence. But a few weeks ago and we could be sure that a large, and rapidly increasing share of all of the editorial letters would have reference to Stock Speculations. So soon as the news of the

action of the Post Office authorities, as given last month, was spread abroad, the whole thing collapsed. We get no more letters asking if Lawrence & Co. and the rest are "responsible," or "will do as they agree." Only the few letters that were then on the way reached us. The movement which led to the suppression of these bogus concerns, was taken by the Law Committee of the Stock Exchange, but their doings have been confirmed

IN A SERIES OF STRONG RESOLUTIONS adopted by the Stock Exchange itself, which has given the Law Committee more power to act on behalf of that body. .... The Post Office Department is doing wonders in the way of the suppression of fraud. The shutting up of these stock swindlers is but a small portion of its good work; it has made the way of the lottery transgressor so hard, that he has been obliged to go over to Canada, and we find the Louisiana State, the Royal Havana, and the Kentucky State Lotteries in Montreal, where they

#### DEFY THE LAWS OF THE UNITED STATES.

The following wriggle and squirm which heads their circular, shows how badly they are hurt.

"TO THE PUBLIC: In view of certain new and recent regulations by which the United States Postal Authorities assume to supervise and decide what class of *mail* matter shall be sent to the citizen, thereby arrogating to themselves a right to interfere with the private correspondence of American freemen, which would not be tolerated by any monarchy in Europe, we have established a General Agency for the sale of tickets in all legalized and reliable Lotteries outside of their jurisdiction."—Merely another illustration of the fact, that "No man e'er felt the halter draw, with good opinion of the law." So far from there being any "new and recent regulations," it only happens, to the great discomfort of scamps of various sorts, that we have a Post Master General who thinks it his duty to enforce the laws made by the representatives of "American freemen," for which these chaps profess so much sympathy, (at the rate of \$10 a package of tickets), and upon whom their bosh about "Monarchy in Europe" is wasted. It isn't the "American freemen" who are at all troubled. It is you

#### VIOLATORS OF THE LAW,

who feel the pinchings of a remarkably tight shoe.... Just as a welcome rain starts into a new growth the weeds as well as the crops, so does the return of "good times," set on foot fraudulent schemes as well as honest enterprises. The mining industry is probably on the eve of a period of development greater than has ever before been known, and taking advantage of this, all sorts of schemes, with no other metallic basis than brass, will be placed before the public. A scheme, with its office in New York with a full outfit of President, Sec'y., and a strong team of Directors, is neatly printed, and the circular shows conclusively, that a few of its \$10 shares would soon make one rich, but the names of the people, are

#### NOT IN THE CITY DIRECTORY!

We like better the "Shakespeare" mining circular, which does not give the name of a single person, but

compensates for these omissions by being headed with the somewhat startling announcement that "The Early Bird Catches the Worm." Our advice to the worm is to keep out of the way.... It seems necessary to repeat our warning about

#### MURDEROUS ILLUMINATING OILS.

See what was said last month about selling recipes with "rights" for people to make a so-called oil out of benzine.... We gave in October last an engraving of a "Solargraph Watch," but that cost \$1—while here is a "Time Indicator" of which one can get four for that price, and can afford to have, as they say in Texas: "any dimensions of time." A "Time Indicator" is advertised for 25 cents. Whoever sends that sum receives a card of the size here given. On one side are neatly printed the lines and figures shown in the engraving. At A is a piece cut so as to turn up and form the *gnomon*, or part of the dial that casts the shadow; a thread with a small brass ring at each end to keep it in place slides in a slit where the months are marked. One has only to set it right when the sun shines—and there it is. This "Indicator" if it doesn't tell the time,

#### DOES GIVE A WHOLESOME LESSON.

Upon the back of the card there is printed as follows:

"NOTICE.—Out of every hundred that order this valuable little novelty, there is generally one that finds fault because he failed to receive an elegant watch prepaid for 25 cents. Of course, if any one expects a 'gold watch full jeweled,' they will find themselves slightly disappointed; but if they expect only the value of their money, they will get it in the article herewith sent."

That lesson is one that a vast number of grown people need to learn, and very cheap it is at 25 cents, with the "Pocket Time Indicator" in the bargain. If some people would only learn that other people do business to make money, and that one way to make money is

#### TO SELL THINGS FOR MORE THAN THEY COST,

a vast deal of trouble would be saved. To illustrate: some rifles are advertised at the very low price of \$4.50, and great numbers write to ask us about the rifle. One would think that no help was needed for a person to decide whether he had any use for a \$4.50 rifle. Every one old enough to be trusted with a firearm ought to know that he will not get a \$50 rifle for \$4.50. It is not in the nature of things that he will get anything that is worth more than what he pays for it. No one can do a profitable business at selling for 75 cents that which cost him 100 cents, and those who are in business do it for profit. A great many feel that they have been hardly used when the thing that they buy is worth just about the price charged for it and no more.... We have occasionally in these columns cautioned persons in visiting cities to

#### AVOID ALL ADVANCES OF STRANGERS.

An illustration of the necessity for observing this occurred not long ago in New York. A young man from the country was asked by a plausible stranger to do him a favor. There was to be a horse auction at which a very fine horse that stranger wanted was to be sold. He, stranger, was known as a horse-dealer and judge of horses, and if he bid upon the horse, others would bid higher, but the young man, being unknown, could buy said horse very low—he, stranger, would pay \$200 for the horse, and young man might buy it for as much less as he could. A nice offer, but young man had no money. "But you have your watch and chain worth \$200—buy the horse, tell auctioneer you have to go to your hotel for the money, and will leave your watch until your return; you have only to bring the horse round the corner into the next street and get the money." The plan was carried out, the young man bid off the horse at \$150—would go for his money, left his watch and chain, delighted with the idea of making \$50 so readily, led the horse around the corner into the next street—but stranger was not there; waited, but stranger did not come—waited longer, no stranger; at last went back to place of sale—no one there! At length it began to dawn on the young man that the horse was not the only thing sold. He was out a valuable watch and chain; was in a horse worth all the way from \$10 to \$15, and a lesson about

#### AVOIDING THE ADVANCES OF STRANGERS,

which was worth all he paid for it.... It is a common trick of quacks travelling in the Western States, to claim to represent some Medical College in N. Y. City, or else to belong to some Medical Institute. We have already shown that no Medical College with a right to the name, ever sends out travelling doctors; the very fact that one claims this, stamps him as an impostor. With Medical "Institutes," the case is different. One man may call his doctor shop an "Institute." There is a chap going about in Ohio, representing the

#### "GREENLEAF MEDICAL INSTITUTE"

of New York City, and his circular has much to say about "Dr. Greenleaf." Friends have written to know about this Dr. Greenleaf and his "Institute." The fact that no location except the indefinite one of "New York City," is the most remarkable display of modesty. This "Institute," is an illustration of the truth of the proverb,

"What is wanting can't be numbered."—As there is no such Institute, the quack who "can read diseases by the tongue," fully represents it.... Last month we spoke regretfully that our beloved Eddie Eastman had passed out of sight. We were mistaken; a friend sends us a New Jersey paper, with Eddie's picture all in his Indian

THE "POCKET TIME INDICATOR."

rig. We have hopes of Old Mother Noble: who knows but *he* may turn up? We always had a half way regard for Old Mother Noble; he didn't like what we said about him, and came in like a man and said so.... The taking of the census will open the way to frauds of various kinds, against which people should be on their guard. Just as we close this page the information comes that one chap—or concern—has already begun operations, by opening

#### A CENSUS INFORMATION BUREAU,

and advertisements have been sent to papers all over the West, which read thus:

"Persons (regardless of politics) desiring situations as Enumerators of the forthcoming Census, can obtain all necessary information by addressing us. One or more, according to population, required in each township. Good salary to competent men. Address

#### CENSUS INFORMATION BUREAU,

No. — Street, Chicago, Ill.  
Enclose 25 cents to insure answer and pay for stamps and blanks."

That is very neatly done; observe that nothing is promised—nothing is very definite about it except that 25 cents is to be sent, and thousands would be the greenhorns who sent, had not the Postmaster at Chicago the power to tell C. I. Bureau, Esq., that he can't have any letters at that shop.

An Unanswerable Letter is one that we have from a young man, who gives us an account of his life and present occupation, which he dislikes, and asks us to tell him what business he had better undertake, and moreover wishes us to find him a situation. We have many times before had requests to find the writers situations, but we think that this is the first time we have been asked to decide upon the business one is fit for, and put him into it besides. With every disposition to aid such persons, it is simply impossible. We can't help thinking that if one does not know what he is fit for himself, he will never find that any one else can discover it.

**Asbestos Liquid Paints.**—Last spring we made a favorable mention of the Asbestos Liquid Paints, after two year's experience with them. Now, after another year's exposure to the weather, we can confirm that report—indeed, we can see no appreciable change during the year, the surface remaining as hard, and as free from "chalkiness" as before. The durability of the paints, as shown by our test, is well established. That they are easily applied, and "cover" well, is shown by their use on elevated rail roads, as the immense contracts for these roads would not have been made, unless these important points had been satisfactorily shown. The makers claim, and with good reason we think, that the covering quality of their paints is due to the fact that, after mixing them to produce the desired colors, they are again ground, and that this second grinding, brings the oil and pigments into more intimate combination, and gives an uniformity of consistence, not to be attained by mere mixing. The paints are furnished of any desired shade or tint, and in a condition to be applied at once, without any previous preparation.

### Pleasant Subscriptions—Far off Friends.

—Few outside of the business office have any idea of the wide range of circulation of the *American Agriculturist*. Here is an item or two: For years past the largest number of subscribers, in proportion to population, have come from Washington Territory, north of Oregon. Over 3,500 copies have gone by mail to subscribers in New Zealand, directly under us—that is, on the opposite side of the world. On Feb. 4th, a single letter called for 80 subscriptions for Barbadoes in the West Indies, while a single previous letter contained 79 subscriptions from Nyne Tal in the East Indies, a thousand miles or so northwest of Calcutta; and so in much the same way we might go round to every habitable part of the world.

### Notes from Shaker Village, N. H.

—The Shakers are such good farmers that we wish they would write oftener. We gather the following from a letter from the Family in New Hampshire. Bro. John Bradbury kept 29 hens the past year. He obtained from these 4,500 eggs, and raised 58 chickens. "He modestly says others in the poultry line may have done better"—we wonder who?... Henry C. Blinn writes that brother R. Woodward is rather proud of his stock, that he has a Jersey bull, 10 months old, that weighs 598 lbs., a Durham bull that, at 9 months, weighs 725 lbs., and a heifer of the same breed that weighs 615 lbs.—But the Shakers are noted for feeding every thing well, whether it runs on two or on four legs—is with or without feathers.

### Oil Stones in N. Carolina.

—In the article in Dec. last, describing the manner of making whet-stones, it was stated that *Novaculite*, as the mineral is called, is found, among other localities, in North Carolina. Mr. W. B. Phillips, Assistant in the Experiment Station at Chapel Hill, writes to say that the most noted locality of the mineral is about seven miles from that place. There are other localities in Person, Anson, and Montgomery Counties, but that at Chapel Hill is of superior quality. There has been no regular working of the quarry.

### Leached Ashes.

—Potash is the principal fertilizing constituent of ashes, and the one that is removed by leaching. The leached ashes contains about one-fifth the amount of Potash of the unleached, the Phosphoric Acid, Lime, Magnesia, etc., remaining about the same in both. A bushel of leached ashes contains not far from one pound of Potash, worth 4 cents, and about the same amount of Phosphoric Acid, worth 7 cents. Allowing something for the Lime, Magnesia, etc., leached ashes is worth in the neighborhood of 12 cents per bushel. If the unleached ashes contains 5 pounds of Potash per bushel, they will be worth not far from 30 cents. A hundred bushels of leached ashes per acre is a good application, and one that is lasting in its effects.

### Mulching a Hedge.

—"M. C.," Albion, Ill., has been told that mulching an Osage Orange Hedge with sawdust is preferable to cultivating it, and asks if straw will not answer for this use. Undoubtedly it would; so long as the material used as a mulch contains nothing injurious it makes little difference what it is, the operation of the mulch being wholly mechanical. Several years ago it was stated that in some of the western nurseries where sawdust was used for mulching, a fungus growth started in the sawdust, which, it is said, injured the young trees. If this is true, straw would be preferable to sawdust. Our correspondent asks if the straw should be partially rotted.—No; ordinary straw from the stack. In absence of straw, tan-bark, swale hay, sorghum bagasse, leaves, chips, or whatever cheap material that will cover the ground and prevent evaporation will answer. He asks: "Should they be mulched when planted, or be cultivated one year?" Mulch at once.

### The New York Horticultural Society

holds its meetings on the first Tuesday of each month, at 2 o'clock P. M., at "Republican Hall," at the junction of Broadway and Sixth Avenue, a place easily reached by both elevated and surface railroads. There is always something interesting to be seen at these meetings, and sometimes the exhibition of flowers, plants, fruits, etc., is really very fine. The exhibitions are free to all, and not only our many city readers, but our friends from abroad who may visit the city at the beginning of any month, should bear these interesting meetings in mind.

### Some Corn in Illinois.

—The corn crop of the single State of Illinois for the year 1879 is reported to be 305,813,377 bushels, and estimated to be worth \$97,483,052, or about 31½ cents per bushel. It is difficult for the mind to take in the full magnitude of these figures. Here are some calculations that will help the conception: Load this corn upon wagons, 40 bushels to the load, and start them off on the road so near together that there shall be 100 teams in every mile. The line of wagons carrying this one crop of Illinois corn would stretch away 76,453 miles, or more than three times around the world!—Again: Load this crop upon railway

freight cars, 285½ bushels or about 8 tons to the car, and make up these cars into a continuous freight train, allowing 30 feet of track to each car. The train would extend 6,080 miles, or nearly twice across the continent, from the Atlantic to the Pacific Oceans!—Again: Suppose we put this corn crop into a square bin 20 feet deep. Let the arithmetical young readers of the *American Agriculturist* reckon how large this bin would be each way. Also, how many acres it would cover.—Also, how many pounds of pork it would make if given to pigs weighing 100 lbs. each when they begin feeding upon the corn, and 250 lbs. when killed for pork.

**Assorting Apples.**—At this season of the year apples will be decaying to a greater or less extent, depending upon the variety, care in picking, handling, storing, etc. If kept in barrels, they may be turned out and the decayed ones removed, after which these that remain had best be spread upon shelves in thin layers, where they may be kept dry, and where the "specked" ones can be removed so soon as they are affected. In this way sound fruit may be had until late in the spring.

### Bee Notes for March.

BY L. C. ROOT, MOHAWK, N. Y.

As spring approaches the risk of injury to the bees by any disturbance is much greater than earlier in the season; hence we should keep the bees entirely undisturbed, or as nearly so as possible. A recent writer has truthfully remarked that it may be said of some colonies that they were "disturbed to death." Over anxiety to examine into the condition of the bees, and to do something which might make them winter well, has brought failure to many an inexperienced bee-keeper.

#### QUESTIONS AND ANSWERS.

**WOOD FOR HIVES.**—A correspondent in Bridgeport, Conn., asks: "What kind of wood is best for hives and frames. Would pine answer?"...Pine is the very best lumber that we have ever used for this purpose, and we know of nothing better.

**TRANSFERRING COMBS.**—Another writes: "Please let me know how to fasten combs that are transferred from box-hives into frames."...The process of transferring is described in the Notes for May 1876, or if a more full and illustrated description be desired, he will find it in Quinby's "New Bee-keeping," where it is given in detail.

**WINTERING BEES.**—A correspondent at St. Johns, N. B., misunderstands our directions for wintering bees. If he will follow closely our instructions as given from time to time in these Notes, and especially those given in our new edition of Mr. Quinby's work on Bee-Keeping, he will find that we urge the necessity for keeping the room containing bees warm and free from moisture. His idea of putting a stove in the room with the bees is open to objections. The stove should always stand outside of the room to avoid disturbing the bees when building the fires. The pipe may be allowed to pass into the apartment if not too near the hives.

**DO HONEY-BEES INJURE SOUND FRUIT?**—This question is one that comes very frequently, and from all parts of the country. It now comes to us from New Jersey, though not in the form of a question, so much as an unqualified assertion, a most positive statement, that unquestionably honey-bees do destroy fruit. This gentleman says that all of his early peaches were destroyed, as were also two-thirds of his grapes, and that "first, last, and all the time" it was the work of honey-bees. The statement is a most positive one, and were it not that we have had extended experience in the matter, and made it a subject of particular study and investigation, should be disposed to hesitate somewhat in taking the part of the bees. That honey-bees are often a source of annoyance to fruit growers, is freely admitted, as it will be by every one who is well informed on the subject. That bees, in times of scarcity of honey, will eagerly take the juice of any punctured fruit, is also a well understood fact. Dealers in fruit and owners of cider mills are often much annoyed by bees. Whenever the skins of fruit, from the occurrence of hot weather after a rain, or from any other cause, become broken, the bees will at once suck the juices from the fruit. I have on my place a Creveling grape-vine, which stands near the corner of a building, in such a position as to be seriously affected by the wind; as a consequence, the fruit becomes broken, and the bees of course sip the juice from it as fast as it is exposed. I have never picked a perfect bunch of grapes from this vine, yet I have many other vines of the same variety, standing in ordinary position, which are entirely undisturbed by the bees, and yield fruit in abundance. The late M. Quinby was not only interested in bees, but also had much interest in fruit growing, having several hundred grape-vines of different varieties. He depended upon these for a good share of his income in seasons that gave a poor yield of honey. If bees were capable of puncturing fruit, it might reasonably be expected that during those seasons, if at all, when little

honey could be collected, bees would be more than ever untiring in their efforts to puncture the fruit. Here was one earnestly endeavoring to find the truth in this matter. He was interested in both bees and fruit, and of course would investigate without prejudice. As a result of his investigations he repeatedly stated that he found the bees unable, in a single instance, to puncture sound fruit of any variety whatever. In 1869, while yet associated in business with Mr. Quinby, our yield of honey was an entire failure, while, on the other hand, our grape crop was particularly fine. At the very time that the fruit was ripening, the bees were actually dying of starvation. Yet at this season, when the bees should resort to the fruit if ever, and when the fruit was far more perfect than usual, and consequently more tempting, in this season, even a less proportion of it was disturbed by the bees than during ordinary seasons. We made our observations on this point with the closest care, yet we were unable to find a solitary instance in which the bees attacked or disturbed the sound fruit in any manner, yet there were hundreds of colonies within easy reach of the vineyard. There is one important thing to be remembered in this matter. Nature has assigned to the honey-bee certain work, and provided it with proper implements with which to execute it. The bee has no piercing and tearing jaws, or any other organ with which it can rupture the skin of a fruit. On the other hand it is a part of the occupation of hornets and wasps (or the majority of them), to build their nests from partly decayed wood, which must be torn from rails, boards, etc. These insects are provided with cutting jaws which are very strong, and of such a form that they can tear even the toughest fruit skins with ease. That careful observer, the Rev. L. L. Langstroth, investigated this matter many years ago, and in his work on "The Honey-Bee" is most emphatic in his assertion that bees are not the aggressors in the attacks upon fruit, and to confirm his statement gives engravings showing the jaws of both the Honey-Bee and Honey Hornet, magnified. These engravings

1.—HONEY BEE'S MOUTH. 2.—HORNET'S MOUTH.

are here reproduced. Figure 1 shows the blunt and unarmed mouth-parts of the honey-bee, and figure 2 the corresponding parts of the honey-hornet.

It is earnestly hoped that, before advising the destruction of bees in any neighborhood, our correspondent will first investigate more closely, and see if the fruit disturbed by the bees is not first injured by other causes. The views here given are not only the result of our own personal experience and observations, but are sustained by many other careful observers whose interests were enlisted on behalf of fruit as well as bees.

**Queen Bees by Mail.**—At the last meeting of the National Bee-Keepers' Association, Prof. A. J. Cook was appointed to induce, if possible, the Post-Office Department to rescind the order excluding queen bees from the U. S. mail. Prof. Cook has been successful, and hereafter the queens can be sent by mail—a very important item to many, especially those living at a considerable distance from an express office.

### Pleuro-Pneumonia in Pennsylvania.

Under the provisions of the Act of Assembly passed last winter, Governor Hoyt placed the whole matter of dealing with Pleuro-Pneumonia in the hands of Sec'y Edge of the Board of Agriculture. Since the first of April, 110 animals have been killed; 31 herds containing 595 animals have been closely quarantined and regularly visited by Veterinary Surgeons; when any animal showed unmistakable symptoms of infection, it was at once appraised and killed. In addition to this, a large number of herds supposed by their owners to be infected, and so reported by them, have been examined, and all cattle imported from Europe have been placed in the hands of the State authorities for quarantine. Since April last, the cost of the work has not exceeded \$2,750, of which \$1,300.50 has been paid for animals appraised and killed. At present but 8 herds are in quarantine, and of these four are considered clear of the disease, but not beyond the danger of communicating it to other stock. All herds are kept in quarantine for three months after the termination of the last case of disease.

**The Michigan Agricultural Society** has just closed its accounts for the year, and with its receipts for 1879, at \$52,447, disbursements \$30,597, and a balance on hand of \$21,850, the organization is on a firm financial foundation. The State Fair is set for September 18-16, but as yet the place of holding it is not designated.

## Science Applied to Farming—LV.

## Field Experiments with Fertilizers.—What Farmers have been Doing.

That the intelligent American farmer may be a good observer, is a fact that has been impressed upon me more forcibly than ever by the reports sent me of Field Experiments with fertilizers last season. As will be remembered, the *American Agriculturist* has proposed, for two seasons past, some series of experiments, and arranged to provide the readers with samples of fertilizers for the purpose, of tested quality, and at prices just covering cost. Each article was put up in a small bag, containing enough for  $\frac{1}{10}$  or  $\frac{1}{20}$  acre, and numbered A. B. C., etc. Every bag had a label giving amounts and proportions of its ingredients. With each lot was sent a pamphlet, containing explanations and directions for the experiments, and blanks on which any who might care to take the needed trouble, were requested to note the results and forward them to me. The firms by whom the fertilizers were put up, supplied numerous sets to their customers; the Vermont Agricultural College distributed a number among the farmers of that State; the Maine Agricultural College did the same, and made several series of experiments on its own farm. Prominent farmers in various parts of the country joined in the enterprise, so that the trials were made from Canada to Florida, and from Maine to Kansas.

I may say that both the *American Agriculturist* and the dealers displayed a great deal of enthusiasm in the undertaking, doing this, as I happen to know, at pecuniary cost to themselves, and with no prospect of gain other than would come with the credit for encouraging the enterprise.

## The Reports and their Value.

The blanks for reporting experiments were sheets, about 12 by 19 inches, having spaces for noting, on one side: (1) Description of soil; situation, kind, texture, dry or wet, depth of surface soil, character of subsoil, etc., etc.—(2) Previous treatment, manuring, and yield.—(3) Weather during experiment.—(4) Fertilizers and how applied.—(5) Method of sowing, planting, tillage, etc.—(6) Other details and remarks. The other side was devoted to details of size of plots, dates of planting and harvesting, amounts, quality, and value of produce in grain, roots, stalks, etc., by pounds and bushels; calculated profit and loss, etc. Nearly seventy of these reports are before me. Some are brief, most are well filled, and many entirely so, while several have additional interesting and suggestive statements covering a number of pages of foolscap, for which there was not room on the blanks.

From a detailed account prepared for the forthcoming Report of Conn. Board of Agriculture, I condense a few statements of plans and results.

## Experiments for Testing Soils.

The principle upon which these experiments is based is briefly this: The chief office of fertilizers is to supply the plant-food that our crops need and soils fail to furnish. It is not good economy to pay high prices for materials which the soil may yield in abundance, but it is good economy to supply the lacking ones in the cheapest way. The most important ingredients of our common commercial fertilizers are *Phosphoric Acid*, *Nitrogen*, and *Potash*, because of both their scarcity in the soil and their high cost. It is in furnishing these that Guano, Phosphates, Bone Manures, Potash Salts, and most other commercial fertilizers, are chiefly useful. Experiments were suggested in which the three ingredients named were to be used, each by itself; two by two, and all three together.

To test the effects of these materials on different soils, was the special, and their actions with different crops the general purpose of these experiments. The ostensible object was to work upon farmers' soils; underneath this lay in my own thought a deeper purpose, to work upon their owners' minds.

## Soils Chiefly Needing Phosphoric Acid.

In Mr. Bartholemew's corn experiment, No. 2, every plot which got Phosphoric Acid brought a good crop for the season; every one without it failed. The Nitrogen and Potash both increased the yield, but reckoning a bushel of corn with its

\* In Experiments 2 and 27, 150 lbs. † At market prices, plus \$5.00 per ton for freight. ‡ Including only those in which farm manures were tested with the chemical fertilizers.

[EXPLANATION OF TABLE.—The above table will repay careful study. Thus, for example, in Experiment 2, the 150 lbs. per acre of Nitrate of Soda, costing \$5.62½, brought no increase of corn: 300 lbs. of dissolved Bone-black (charred bones superphosphated) added nearly 29 bushels at a cost of \$5.25; while the two together (D) added 33 bushels at a cost of \$10.88, and 150 lbs. of Muriate of Potash with these making the "complete" chemical fertilizer (G), increased the yield by 38 bushels, at a cost of \$15.38.... In Experiment 6 this last mixture increased the yield by 72 bushels. While this complete fertilizer was so profitable in No. 6, and the Superphosphate in No. 2, in No. 24 the Muriate of Potash (C) paid best, bringing about the same increase alone as with the other materials. In Nos. 1 and 7, all the fertilizers were failures; in No. 1 apparently because of drouth; in No. 7 for some unexplained reason. Taking the average of the experiments for 1878 and 1879, the "complete" chemical fertilizer brought the largest crops of both corn and potatoes, excelling the farm manures. The mixture of Superphosphate and Potash Salts brought nearly as large yields of corn and larger of potatoes than the farm manures. As to average profit, among the chemical fertilizers the complete fertilizer (G) paid best for potatoes, and the mixture of Superphosphate and Potash Salts (F) for corn.

stalks at 80 cts., neither increased it enough to pay the cost. This experiment was made on a field adjoining that of the experiment reported for 1877 and 1878, in which the crop rose and fell with the Phosphoric Acid, while it paid very little attention to the other ingredients. Indeed, in Mr. Bartholemew's experiments, which have now continued for three years, covered nearly one hundred plots, and are among the most instructive ever made in this country, the testimony in favor of Superphosphate, and against the other materials for corn is unanimous, but for potatoes, the complete fertilizer has proved profitable. And for corn, Superphosphate and farm manure together have brought the best results. A number of other experiments have equally striking results with Superphosphate. There are, however, many

## Soils which respond well to Potash Salts.

In Mr. Sage's experiment, No. 24, for instance, no plot without Potash gave a profitable increase, and no one with it failed to do so. This tallies well with his experiments on other parts of his farm in 1877 and 1878, where the Potash Salts paid more than tenfold their cost. The mixture of Superphosphate and Potash Salt, F, which Mr. Sage estimates as costing no more applied than the simple hauling of stable manure to some of his fields, has uniformly brought from 60 to 70 bushels of shelled corn per acre.

## The Complete Chemical Fertilizer.

No. G. has brought by far the best results. It was generally the most profitable of all with pota-

atoes, and often so with corn and other crops. The chemical fertilizers have not only brought larger yields than the farm manures, but have also proved more certain, both in favorable seasons and in cold, wet, and drouth.

## Cases in which None of the Fertilizers were Particularly Useful

are common; No. 7 is such a one. Indeed, these experiments illustrate very forcibly a fact which few farmers appreciate, namely; that there are a great many soils which will not pay for the use of artificial fertilizers, at least until they are better tilled, irrigated, drained, or otherwise improved. In short, the reports before me are full of illustrations of the important facts that:

1. Soils vary widely in their capacities for supplying crops with food, and consequently in their demands for fertilizers.

2. Some soils will give good returns for manuring; others, without previous amendment, by draining, irrigation, tillage, or use of lime marl, or otherwise, will not.

3. Farmers cannot afford to use commercial fertilizers at random, and it is time they understood the reason why.

4. The right materials in the right places, bring large profits. Artificial fertilizers rightly used, must prove among the most potent means for the restoration of our agriculture.

5. The only way to find what a soil wants, is to study it by careful observation and experiments.

6. Success in farming, as in other business, requires the use of brains. W. O. ATWATER.

## Fencing and Fences.

### Wooden Fences.

A large number of descriptions, drawings, etc., of wooden fences have recently come to hand. Some of them are interesting, and we shall keep them for further reference and some of them for use in this Journal. Just now we are giving special attention to the subject of *metal fencing*.

### About Patents on Fences.

A multitude of inquiries, too numerous to answer individually, come to us from all over the country, some describing well, and some unintelligently, various devices, and asking our opinion if they are "patentable" or worth patenting. In most cases it would require careful, thorough examination at the Washington Patent Office to answer these questions, and we can not undertake such work.

### An Important Change of Circumstances—A Great Rise in Price of Iron and Steel.

Since this series of articles on Metal Fences was planned during our summer trip through the West, there has been a very rapid and great advance in the price of Iron and Steel. In September, 1878, the Standard No. 1 Anthracite pig iron was selling at \$16@17 per ton, and in September last it had only risen to \$22@23—that is, to a trifle over one cent per pound. The last week in January it sold as high as \$43 per ton, and to-day (Feb. 6) is quoted at \$40@41—an advance of fully 90 per cent, or nearly double since last September 1. This has resulted from the great demand arising from the wonderful revival of business that took place as soon as our large crops were secured and the generally poor condition of crops throughout Europe became fully ascertained. This demand enables iron producers to charge their own prices, and they are realizing enormous profits. Such a state of things may continue for a moderate period, but when all the idle furnaces are in operation, and the new ones projected are in full blast, prices will be likely to fall back to figures affording only a fair profit. As a very large part of the cost of iron and steel fence materials depends upon labor, patent royalties, etc., the actual cost of metal fencing has not advanced correspondingly, and will not do so. Yet this rise materially affects, for the time being, the progress towards securing *Iron Fence Posts* that can successfully compete with wood for ordinary farm use. But even at the present value of iron, there are, or soon will be found, *iron posts* which will be more economical than to use wood posts at a nominal price.

### Iron and Wood Posts Compared.

Suppose we take the present cost of Iron posts at 50 cents each. Several are now offered at this rate and under. The tables last month (page 51) estimated 100 rods of Post and Board Fence at \$100; and of wire fence with wooden posts at \$67.25. Taking similar figures we have

FOR 100 RODS OF FENCES:			
(Galvanized Steel Wire or Strap, 4 Strands High.)		IRON POSTS.	
WOOD POSTS.		IRON POSTS.	
400 Rods Wire, at 11¢.....	\$44.00	400 Rods Wire, at 11¢.....	\$44.00
100 Wood Posts, at 12½¢.....	12.50	100 Iron Posts, at 50¢.....	50.00
400 Staples.....	7.50	Labor about.....	7.50
Labor about.....	15.00		
Total.....	\$72.25	Total.....	\$101.50

Two men with a single horse and wagon should distribute the material, *drive* the iron posts and put up 100 rods of wire in two days, at a cost of \$7.50. This gives a cost for iron posts over wood of 30 cents per rod (less than 2 cents per foot). But for the increased outlay to start with, we have a *permanent* fence, one occupying the smallest possible amount of ground, one scarcely needing any repairs for half a century, and one indestructible by fire. We are quite sanguine however, that with the present interest and the great activity of inventive minds, we shall very soon learn of some form of iron post that will be both effective and cheap, at a cost considerably below 50 cents each.

### Non-Destructible, Non-Combustible Wooden Posts.

We are glad to learn that hopeful experiments are now being made towards producing a wood fence post that shall be both non-combustible by any ordinary fire, and practically non-destructible

by the weather or ordinary decay, and at an increased expense of only a few cents per post. The information is private and confidential as yet, and we can not judge as to the probable success, but we do not see why, with the Kyanizing process long successfully practised, and with the new application of asbestos there should not be valuable results in the direction indicated. Perhaps by applying such improvements to the cheaper, more abundant varieties of wood, we may get such prepared posts at about the present cost of those made from cedar, chestnut, and like comparatively durable timber.

### Other Forms of Posts.

A very large number of suggestions have recently come to us in the way of new forms, or supposed new forms, of iron posts. Some of these are covered by those already before the public; more are impracticable on account of their expensiveness; some are not clearly described; a majority, while sending queries, insist upon their ideas being considered private and confidential until they have further developed them or obtained patents.... In figures 22, 23, 24, 25, are suggestions of our own, somewhat in the line of figure 11 (Jan. No., page 10)—and we offer these only as suggestive. The above-ground post (fig. 26) is to be a simple flat bar of wrought iron, say 1½ inch wide, ½ inch thick—or of whatever size may be required for the particular fence to be put up: to be notched or pierced for attaching the horizontal lines; to be 4 to 4½ feet above ground, and

Fig. 22. Fig. 23. Fig. 24. Fig. 25. Fig. 26.  
[The small section cuts at the top are not for use, but merely to show the form more plainly.]

extend down as deeply as may be needed by the firmness of the soil, the kind of foot-piece used, the nearness of the posts together and the consequent strain upon each. The ground, or Foot-PIECE, to be made of clay and burned the same as brick, or it may be made of hydraulic lime and sand.—Figure 22 is a simple round tough brick, say 4 to 5 inches in diameter, and 15 to 20 or more inches long, with an opening in the center to receive the iron bar. A little thin hydraulic grouting will hold it firmly in. If burned to vitrification it will be as tough as iron, and absolutely indestructible. A post auger will quickly make an excavation for its reception in ordinary soil.—A Foot-piece 4 inches in diameter and 19 inches long would require the same clay as three ordinary brick of 8x4x2½ inches dimensions.—A piece 5 inches in diameter and 20½ inches long would equal four ordinary brick in contents.—To save weight and clay, this piece may be made as in figure 23, the core only so thick as needed, with three flanges projecting an inch or so; or better still like figure 24, with wedge-shaped flanges, as in this form the piece could be driven with a wooden mallet into a hole made to fit the round central core.—Figure 25 shows the same with *four* flanges.—Figure 26 shows the post set with the iron bar.

### A Primitive Cast-Iron Post.

Henry Gaylord, of Cheshire, Conn., sends us a description of a very simple iron post, made by Sterling Bradley of that town many years ago. These were merely flat cast-iron pieces, three-fourths of an inch thick or so, three to four inches wide. Holes were dug of any desired depth and width, the posts set in, the holes filled with small cobble stone, and grouting (thin hydraulic mortar) poured in. Boards were used for the running pieces,

wire not having come into use. These posts, after standing 20 to 25 years, still remain firm. We give the above as suggestive only. Where small stones abound and hydraulic lime and sand are readily obtained cheaply, it may sometimes be practicable to use a small single bar of wrought or cast-iron of the strength needed, and fasten it firmly in the ground by putting around its base the necessary amount of grouting mixed with small stone or gravel. Notches or holes in the bars will serve for attaching the running wires. For general fencing, posts are required that can be quickly *driven*.

Fig. 27 shows a form of iron post manufactured by A. G. Powell & Co. (see advertisement). It consists

Fig. 27.

of an upright post of wrought iron, one-and-a-half inch wide, and five-sixteenths of an inch thick; 6 feet long, and notched and pierced with small holes for attaching the running wires. This is driven into the ground, say 20 inches. An angular looped collar is slipped down to the surface of the ground, and two shorter pieces of iron 1½ inch wide, one-fourth inch thick, and about two feet long, are driven through the collar-piece, as shown in the engraving, to form braces. This appears like a somewhat effective post—perhaps too expensive for general farm fencing at the present advanced cost of iron. The weight of the whole is about 14½ lbs.

### An Important Point in Favor of Wire Fences

is referred to by several of our readers, which, summarized in nearly the language of one of them, runs thus: "I raise winter grain mainly, and my fields are subject to snow-drifts. Formerly I usually lost a pretty wide strip of wheat along the wooden fences, owing to the heavy snow-drifts remaining so long on a strip two to five rods wide on at least two sides of the field. I have now four ten-acre fields fenced with barbed wire and small cedar posts. These do not check the wind so as to produce snow-drifts, and I save wheat enough to pay the cost of the wire in every two or three crops, while the fence will outlast half a dozen rail fences, I think. Two of these fields adjoin pasture fields, and on the sides next these pastures I have spiked slim long poles upon the posts about 3 feet from the ground. While these do not stop the snow, they warn off the animals, and so far I have had no accidents."

Another correspondent writes that his fruit trees were often girdled by mice that found good winter quarters in the snow-drifts along his old wooden fences. Two years ago last summer he substituted wire fences, partly barbed and partly plain wire, and has had no snow-drifts and no trouble from mice, by taking the precaution to remove or trample hard any considerable bodies of snow that gathered around the trees; and further, that since the removal of the wood fences the mice have had no breeding places, and they have mainly disappeared, so that this winter he will not take any trouble with the snow around the trees.

### Specific Loss and Gain.

A Subscriber in Central New York, states figures thus: "In autumn of 1878, I sowed winter wheat in a field with a high rail fence on one side, 70 rods long. The snow-drift killed a strip full 4 rods wide, or 280 rods—just 1½ acres. The rest of the field averaged 24 bushels per acre, and I sold my wheat at \$1.45 per bushel. The 42 bushels lost by the snow, were worth \$60.90. Here was a loss on one crop of enough to have built a new wire fence, with iron posts, along the whole 70 rods—a fence that would be permanent for a life-time, and need no repairs.".... Another writes from Wisconsin: "I have fields fenced with wood, and others with wire. My observation is, that the latter can on the average be worked at least a week earlier in spring; the former

is wet and cold on the borders, long after the rest, owing to the snow which has been caused to lie in drifts by the wood fence. The wire fence does not produce perceptible snow-drifts."....

#### Injury from Barbed Wire.

In our closing remarks last month (page 52), we said: "None of the long, sharp-pointed barbs having perpendicular sides, or those nearly so, and none of those inclined in any direction to act partially as hooks, are adapted for use along high-ways or where clothing will be likely to come in contact with them. None of the above barbs are adapted to small inclosures, or where valuable animals are in danger of contact with the long, sharp points of any form. Though they may be so shortened as to remove danger of fatal injury, disfiguring sores and scars will be produced. Something in the form of the 'Brinkerhoff Improved,' with sides so inclined as to prevent catching and tearing, and so short as not to produce deep incisions when struck squarely, will need to be provided."... We repeat this with emphasis, and say further, that while the strongly-barbed wires may probably be advantageously used for the large pastures of the West and South-west, we do not advise their use generally where farms are divided into smaller fields and where valuable animals are kept. For all such locations, strong wires, or straps—perhaps with barbs so blunt as to be incapable of cutting or tearing the skins of horses and cattle, or of tearing the wool from sheep—will come into use. We have received many communications, some detailing injuries, and others approving the barbs, of which the following two are given as average samples:

Mr. R. C. McWilliams, an old subscriber of the *American Agriculturist* in Northumberland Co., Pa., personally gives us items from his experience with barbed wire fence. He has not discarded its use, and does not absolutely condemn it; hopes the embankment described last month (page 52), or some other device, will render it less dangerous. He had a valuable cow that had one leg cut down to the bone, "nearly half off," and the flesh badly torn by the fence barbs. She was a long time in a dangerous condition. A \$200 horse had both legs cut, and a wound on the side. He had paid \$18 for a Veterinary Surgeon's attendance, had the horse laid up 3 months, and it was not well yet. He thought the present value of the horse might be \$50 for ordinary work when fully recovered, though he could only get an offer of \$30. His father-in-law, Dr. Jacob Reigard, of Ogle Co., Ill., has a half mile of barbed fence, and though not entirely satisfied with it, does not condemn it.

H. L. Raven, of Travis Co., Texas, writes us: ".... As to the injury to live stock, which seems to be the great objection to barbed wire here, my own experience is that the danger is not of great extent. I have had no serious accidents. Only one horse has scratched itself, though I have put into the pasture horses that had never seen a wire fence. But it is best to be careful and not crowd animals towards these barbed wires until they learn where they are. Barbed wire will be a great boon to Texas, enabling us to put into cultivation large tracts of land that would have lain idle without it...."

#### Further Forms of Barbed Fences.

Partly as a matter of curiosity, and especially to stimulate further thought and invention, we pre-

in the engraving.—No. 33, comes from a reader in St. Paul, Neb., who withholds his name. It differs from No. 32 only in the form and size of the barb, which in the pattern is less than an eighth of an inch wide, and not quite half an inch long. They are 2 inches apart, turned out on opposite sides, and the strap twisted when put up. Our corres-

No. 33.

pondent refers us to Purdum & Reed, of Chillicothe, O., for further particulars.—No. 34 is from a pattern sent us by Geo. N. Hodgdon, Nashua, N. H. This is similar to No. 32 in the form of the barb, but the barbs are cut singly every 2 inches, instead of in pairs every 5 inches. The steel strap is galvanized and twisted in putting up.

No. 34.

While all three of the above (Nos. 32, 33, 34), are open to the objection of having cutting barbs, the strength of the strap is lessened somewhat in No. 33, and largely so in 32 and 34—fully one-third—and the strap would need to be fifty per cent wider to secure the same strength. The "Brinkerhoff Improved" (No. 19), retains the full tensile strength

No. 35.

of the strap, requires only a small amount of metal for the added barbs, and these can be made so blunt as not to cut or tear.—The prominent advantage of the strap over the twisted wire is that the former is more conspicuous—more readily seen by animals approaching it. Several other forms of barbs, used on wire, can be much modified in length and sharpness without destroying their efficiency.

No. 35.—"King's Thorn-Stay Fence" is one of the varieties of barbed fence we have not before exhibited. It is the ordinary plain wire fence of three strands of No. 9 wire, to which are fastened, with staples, a series of inch square wooden strips, or "stays," set inclined as shown in the engraving, and placed alternately on both sides of the horizontal wires. The staples pass through the stays, and are clinched on the side opposite the wire. The wooden stays are also supplied with pointed barbs. It is claimed that these wooden pieces render the fence visible, support the wires, preventing their being spread apart by animals attempting to crowd through, and that the barbs thus placed are less liable to be seriously injurious. Before the recent rise, these stays were supplied at \$2.50 per 100. Their expense will of course depend upon the distance apart they are placed. Aside from any advantage or disadvantage of the barbs, such strips or stays, if thoroughly protected from decay, and without or with barbs, could be applied along plain wire fences already built, and be placed a few inches or a few feet apart, as desired. These stays are made in Iowa by the Baker Manufacturing Company.

The White Pine Weevil.—A few insects are of benefit to the plants upon which they feed. Mr. A. S. Fuller, one of the editors of the "American Entomologist," cites the White Pine Weevil (*Pissodes strobi*), as an insect of undoubted use to the trees upon which it makes its home. The grub of the weevil perforates and kills the leading shoots of young pines and spruces, thus checking the up-

ward growth of the main stem, when the branches below bend inward, and grow more vigorously, thus causing the tree to assume a better shape than it would otherwise—a sort of natural pruning which such trees often need but seldom get. Mr. Fuller says: "Since the advent of the Pine Weevil on my place many of the Norway Spruces have been greatly improved in their appearance by the almost annual destruction of the terminal or leading shoots, and no one would question the benefit of this kind of pruning after a glance at the trees, comparing the weevil-pruned with those that have escaped. I have only to regret that these insects do not visit every specimen on my grounds, for it is no easy task to get at the leading shoot of a Norway Spruce 30 or more feet high, and take it out with a knife or shears." When the trees are young, as those in nursery rows, the insect may do some damage.

#### Simple Plumbing for a Kitchen.

The engraving herewith illustrates a practical method of plumbing for country houses. It is quite free from complications, and the several parts may be obtained ready fitted, so that with pipe-long and a screw-driver, any mechanic should be able to connect and set up the whole in working order. The cost is small. For the house on the next page it is estimated at \$40; but may be considerably lessened. The annual interest and depreciation would not be over \$5, while the saving of the house-keeper's strength would be many times that sum. A is a "ship pump," fastened to the kitchen floor, and afterwards enclosed by the wood-work fronting the space beneath the sink, so that when finished no part is in sight except the handle, which extends upward, and is worked with a lateral motion through a slot made in the drain-board. Other forms of fore-pumps may be selected.—B, B, 1-inch supply pipes leading from a cistern to the pump, and thence 3/4-inch pipe to the tank. C is a branch from the supply pipe leading to a point 10 inches above the sink, where a faucet is attached to regulate the flow of water as required. The tank, D, having capacity for 3 hogsheads of water, is placed in second story immediately above the pump. It is of plank, firmly made, and lined with sheet lead. E, iron sink, 16 by 24 inches. F, waste pipe (1 1/2-inch with trap) leading from sink to a drain outside. A hogshead might take the place

Fig. 5.—PLAN OF PLUMBING FOR A KITCHEN.

of the tank to save expenses, but is less desirable. The above very simple, easily constructed and inex-

No. 32.

sent in numbers 32, 33, and 34, the independent suggestions of three of our readers, living remote from each other, in different States: No. 32, is engraved from a pattern sent us by H. H. Hagerman, of West Windsor, Ohio. Two barbs are formed by puncturing out central portions from steel straps, every five inches, and bending these portions at right angles to the strap on alternate sides, as shown

pensive plumbing arrangement should be included in the fittings of every kitchen, as one of the most valuable and sure helps possible to obtain for its cost. A few moments spent in filling the tank

Fig. 1.—FRONT ELEVATION OF HOUSE.

as needed, by some hand employed on the place, will give abundant supply of water for all ordinary uses, and greatly lessen the labor of house-work. An opening may be made through the kitchen ceiling below the tank, which will allow sufficient heat to pass up to protect the tank water from freezing in severe weather.

### A Farm House Costing \$1,200.

BY S. B. REED, ARCHITECT, CORONA, LONG ISLAND, N. Y.

This plan is partially based upon a sketch of a Wisconsin Farm House at which Mr. Judd stopped during his recent Western travels. It is suitable to most places in this latitude, and may properly front the north, east, south, or west. The interior is adapted to the wants of an average sized family. As is usual in this class of buildings, all halls, and expensive stairways are omitted, the entire space being devoted to the uses and convenience of the family....**Elevation** (fig. 1).—The general outlines and style are such as predominate on the buildings of thrifty farmers everywhere, and are suggestive of comfort and modest pretensions.

The details of exterior finish are very simple, and arranged for good proportion....**Cellar** (fig. 2).—Height in clear, 6 feet 2 inches. It is lighted by five small windows, has an outside entrance from the rear, and stairs leading to the work-room of the first story....**First Story** (fig. 3).—Height of ceilings, 9 feet. There are four good sized rooms, three closets, and the necessary stairways. The Parlor is square, has two front windows, and may have a side window at the right. It has an open fire-place and a mantel. The Kitchen is also square, has windows overlooking on three sides; an open fire-place suitable for a range; two closets, and a sink and pump. The Work-room communicates directly with the kitchen and with the cellar under the main stairway, and has an outside door opening to the rear stoop. Some use this room as a kitchen and the other as a dining and family room. In such case the sink and pump may be placed at A, and a stove at B, with smoke-pipe connecting with the chimney flue from the second floor. The Bed-room is convenient to either parlor or living-room, and has two windows and a closet. The Stairs, both up and down, are arranged to occupy

little room, and have doors to each....**Second Story** (fig. 4).—Height of ceilings in the main part 8 feet, in the side wing 3 to 6½ feet. They may be carried higher if desired at small additional expense. There are two chambers, two closets, and a passage in the main part; two bed-rooms in the side wing, and a garret in the rear wing, all opening from the stair landing. The Chambers have side walls full height to the ceiling, the Bed-rooms are "half-story" finished. The Garret is floored, and has a small window in the rear, but is otherwise unfinished, being intended as a place for general storage....**Construction**.—The excavations for the Cellar are 4 feet deep. The Foundation and Chimneys are of brick-work. Frame of sawed timber; Siding of "Novelty pattern," which is preferable, but may be of other form of hoards. Principal roofs of shingles; Veranda and Porch Roofs of tin. Floors of 8-inch spruce, tongued-and-grooved. Windows in cellar have three-light sash hung with butts. Other windows have eight-light sash hung to weights. All doors are four-paneled. Casings for the first story are 5-inch moulded; for second story, 5-inch plain; Base to match casings. Plastering of both stories, two full coats and white finished. Painting, two coats of best materials. A pump, sink, and tank are provided, connected with suitable pipes, figure 5. (See article on the preceding page.)

In the following estimate many items may be reduced in some localities, as, for example, the foundations may be of stone, where easily obtained; and where lime and sand are cheap the plastering would be much less....**Estimate**:—**Cost of materials and labor**:

37 yards excavation, at 25c. per yard.....	\$ 14 25
12,000 Brick (furnished and laid), at 12c. per M.....	144 00
30 feet stone steps, at 12c. per foot.....	3 60
475 yards Plastering, at 25c. per yard.....	118 75
2,500 feet Timber (as follows), at \$15 per M.....	42 00
2 Sills 4x8 in., 26 ft. long. 5 Posts 4x7 in., 10 ft. long.	
6 Sills 4x8 in., 15 ft. long. 2 Posts 4x6 in., 13 ft. long.	
2 Sills 4x8 in., 13 ft. long. 2 Plates 4x6 in., 26 ft. long.	
2 Ties 4x6 in., 26 ft. long. 3 Plates 4x6 in., 15 ft. long.	
3 Ties 4x6 in., 15 ft. long. 2 Plates 4x6 in., 13 ft. long.	
1 Veranda 3x7 in., 56 ft. l'ng. 40 Beams 3x8 in., 15 ft. l'ng.	
14 Beams 3x7 in., 13 ft. l'ng.	
100 Joist 3x1x13, at 15c. each.....	15 00
200 Wall Strips, 2x1x13, at 11c. each.....	22 00
230 Novelty Siding Boards, at 28c. each.....	64 40
Cornice materials.....	20 00
300 Shingling Lath, at 6c. each.....	18 00
33 bunches Shingles, at \$1.25 per bunch.....	43 75
150 Flooring Plank, at 28c. each.....	42 00
2 Stairs (complete).....	15 00
5 Cellar Windows (complete), at \$3 each.....	15 00
15 Main Windows (complete), at \$7 each.....	112 50
15 Doors (complete), at \$6 each.....	90 00
3 Mantels and Shelves (complete), at \$2 each.....	6 00

Verandah and Stoop (complete).....	30 00
Pump, \$10; Tank, \$15; Pipes, \$8; Sink, \$2; Setting, \$5.....	40 00
Carpenter's Labor not included above.....	150 00
Painting, \$120; Carting, \$15; Incidentals, \$25.25.....	160 25
<b>Total cost, complete.....</b>	<b>\$1,200 00</b>

### Materials for Compost.

The compost heap is always a timely topic, and the heap itself should be kept going from the beginning to the end of the year. Only put the right materials into the mass and it will make money for us while we sleep. There is generally time

Fig. 3.—THE FIRST STORY.

for the gathering of these materials before the spring work is pressing. Acres of rich material lie in every forest, the decaying leaves and fallen branches of many generations, often within easy reach of the barn, or of the field that is to be cultivated the next season. This mass of leaves and leaf-mould is rich in potash and phosphates, and is just what long cultivated fields and gardens need to increase their fertility. With a little calculation, muck, peat, or headlands can always be made available for the compost heap. This bank will never fail to give dividends. Any decaying vegetable matter—old straw, bog hay, corn stalks, saw dust, chip manure—may safely be put into the compost heap. Any animal matter in sufficient quantity will start fermentation in the heap and add to its value. If other articles fail, fresh manure from the stable and yard or sty, is always available upon the farm for this purpose. On most farms there are other occasional resources in dead animals, that should not be overlooked. The market town and village should be made to contribute to the compost heap. Wood ashes are sometimes available, the factory has woollen wastes, the grocer spoiled

Fig. 2.—THE CELLAR.

The wood-work is set 2 feet above the grading, giving room for cellar windows and insuring dryness of the interior. A Veranda is always pleasant and useful to protect the front entrance from sun and rain. If desired, a vestibule can be had by enclosing the space as shown by dotted lines (fig. 3), and a door could open from it directly to the parlor.

Fig. 4.—THE SECOND STORY.

fish and meats and old brine, the builder slacked lime, and even the gas company gas lime. Slaughter-house refuse is rich in blood and animal matter, which is very valuable. The team that carries a load to market, in the absence of a paying load home, should bring back something for the compost heap.

### Swiss Dairying.—The Simmenthal Cow.

Switzerland is essentially a dairy country. The grass grows greener upon the sides of the Swiss mountains, and in the elevated valleys than elsewhere, not excepting even the noted meadows and pastures of Ireland; the "Emerald isle," so-called from its luxuriant verdure. These verdant pastures have helped to produce some of the best Short-horns, as those of Switzerland have produced the Swiss cows, probably the most prolific of milk and butter of any race of dairy animals. Pastures make cows; time and breeding of course being indispensable elements in the process, but no length of time or system of breeding can build up a race of excellent dairy cows without the feeding. The Swiss grass lands are favored with special advantages. The winter's frosts loosen from the granite rocks the most important elements of fertility, of which potash is the chief one, and the spring thaws and summer rains wash these down the hillsides and over the valleys and supply perennial sources of mineral food to the grass. Nowhere else is this natural process of fertilizing going on continually on a grander scale than in that country, where mountain side and sheltered valley alternate with surprising frequency. The rich verdure; the pure air and water; the freedom from restraint; the gentle and familiar tending; in short, the perfect adaptation of condition and circumstance to the development and comfort of the Swiss cow is such that it is noticed as a general thing that these animals, when taken from their homes, suffer from a sort of "home-sickness"; they lose their contented disposition, they seem to fret, and rarely fail to depreciate in excellence during their enforced banishment. It is only when their progeny become acclimated and used to the new circumstances, that the race recovers its historic value and meets the expectations of its new owners. This fact, which is too frequently observed to be doubted, has led to the opinion among Swiss dairymen that the exportation of their cattle should not be encouraged, and among the French dairymen that importations of these mountain cattle do not turn out so satisfactory at first as might be expected. It may be that a sort of sentimental patriotic feeling so general among the

leave their pastures and herders, as they themselves could leave their homes; and only with equally regretful memories. But, however, the fact remains, that pastures and cows being perfectly adapted to each other, the Swiss cows in their native homes are perfect dairy animals. And this is true with all the varieties of this race, of which there are sever-

figure of the bull is that of a true dairy animal. The breed possesses large milking capacity, and cows that produce 34 quarts daily of very rich milk, are said to be by no means unusual. But it is a common failing for the breeders of a race of cows, to strain a point in favor of their own kind of stock, and it is remarked by a well known Swiss

Fig. 1.—A SIMMENTHAL (SWISS) BULL.

al. The *Simmenthal*, the subject of the portraits here given, is to other Swiss cows, what the Jersey is among our dairy cows. An average product of a Swiss cow is 2,700 quarts in the year, a comparatively low yield, but the milk is exceptionally rich in cream. The best cows give 28 to 32 quarts per day when fresh, and an average of 18 quarts through the pasturing season, is far from rare. The Sim-

writer, that as the question of profit is closely connected with the reputation of a race of cattle, attempts are sometimes made to obtain a high character for one breed, at the expense of others, with a view to attract purchasers; a remark which may be justly applicable to others than these simple mountaineers. The same writer also hints strongly of "intestine quarrels;" "interested eulogies;" and "accusing controversies;" all of which might well be supposed to apply to other advocates of different kinds of dairy cattle than the Swiss, who are as yet unable to agree among themselves, as to which of their various breeds produces the best dairy cows. Our American breeders find themselves in a similar predicament. The Swiss cows, more especially the variety known as the *Simmenthal*, have been fed and bred for the production of rich milk. It is an accepted belief among Swiss breeders, and dairymen, that feed is a very important element in the production of butter. The faculty of converting certain elementary substance into butter is organic, depending on the structure, and constitutional functions of the cow, and being independent, up to a certain point, of the nutriment. Of two cows fed alike, one may give richer milk than the other. It is curious that this evident, and practically known fact, should be disputed by some persons, (not Swiss), who are taken to be experts on dairy matters. But facts show it to be true in spite of theories and opinions; and our readers, who guide themselves by any other principle than this, will surely discover that they are misled. Swiss cows, by reason of their excellence, have been largely exported. The spread of the manufacture of Gruyère cheese—for which rich milk is necessary—into those districts of France and Germany, which border on Switzerland, has made it necessary to import with the industry, the means to make it successful, and where this cheese is made, the Swiss cows, and Swiss dairymen, have been introduced. The race has taken a permanent foothold in America, and several herds of the most excellent quality are now in course of formation in parts of New England. For the photographs, from which the accompanying portraits are reproduced, we are indebted to one of our Swiss subscribers, Mr. Im Obersteg, of Oberwyl. The cattle were bred by Mr. Rebman, in Erlenbach. The bull is 3 years, the cow 5 years old. Both were sold to a Russian.

Fig. 2.—A SIMMENTHAL (SWISS) COW.

Swiss, may have given birth to this idea of "home-sickness," when in reality it is not so much in the sensitiveness of the *morale* of the cow as in her digestive organs, not so richly supplied, that her failure has its origin. Perhaps, too, the inventive minds of the Swiss people, to which the far-famed legend of William Tell, with all its amplifications, is due, in their absorbing love of their own land, may have imagined that their cows can as hardly

menthal cow, as seen by the portrait given, is essentially a dairy cow. The gentle expression and the quiet attitude produce a favorable impression at first sight. Having an excellent reputation, it is frequently the case, that other cows of mixed breed, similar in color, are passed off as of this variety, and this may be taken as one proof of its excellence. The color of this breed is red, pale-red, or red and white; the whole appearance is pleasing, and the

### Smoothing Drags and Pulverizers.

The success of any crop depends greatly upon the proper preparation of the soil, which should be made fine and mellow, but yet compact and firm about the seed. It is better to spend two days work than one in preparatory fitting of the soil for a crop, because the extra labor will be liberally repaid by the better growth, from the first sprouting of the seed and the lighter labor of cultivating afterwards. We have recently examined an excellent implement for this work, the "Acme Pulverizing Harrow, Clod Crusher and Leveler." This consists of an adjustable bar in the front (see fig 1), which is moved by the lever so as to ride over the clods in

Fig. 1.—THE ACME PULVERIZER AND LEVELER.

rough ground and crush and break them by means of a number of teeth fitted into it. Behind this is a second bar furnished with steel blades, which cut the soil, pulverize it, and turn it in small furrows, leaving it in the best possible condition, covering weeds or sod perfectly. We find this machine to be adapted for other uses than are claimed for it by the makers. There is no better implement for covering seed, especially peas, which are difficult to cover by the common harrow; and the ground is left in the best condition for sowing grass or clover seed, after the seed grain is covered. By adding markers behind it it may be made very effective in marking out rows for planting corn, or drills for sowing beets. A coverer for grass seed sown after this implement is shown at figure 2. This may also be used for packing the soil in place of a roller, and on light soils will be found far more useful than that

Fig. 2.—COVERER FOR GRASS SEED.

implement. It consists of a number of rails or poles fastened together by means of two light chains. If desirable, markers may be attached to this implement in a manner shown in the above engraving.

**Milk—What is It?**—The natural food for the young of all mammals is milk—a rather complex fluid, the physical properties of which it is not necessary to describe.—The principal constituents are water, sugar, caseine, albumin, fat, and several salts. The sugar, when separated, looks much like the ordinary kind from the cane, but is much less sweet. Caseine is one of the leading constituents, and is the part which, when removed from the milk, becomes the cheese. The caseine exists in small particles in the milk, and is contracted or gathered into large masses by the action of acids or rennet. The albumin remains in solution after the caseine is removed, and is separated by boiling, when it appears as white curds, somewhat resembling the white of eggs in appearance, as it does also in composition. The fat is not dissolved in the milk, but suspended as little globules with thin coverings. In the process of churning, these globules are

broken, and the fat collects in lumps of various sizes. This fat, when worked, salted, etc., is the butter of the market and table. The ash is but a small part of the milk, and consists of a number of substances, which are left behind when the milk is dried down and burned. There are many things to influence the percentage of these various ingredients of milk. It is far from the same in different species, and among cows, the breed, feed, general treatment, age of animals, etc., all have a modifying influence.

### Ventilation of Barns and Stables.

The moist air of barns, and the foul air of stables, should be carried off in the most direct manner. Ventilation depends upon the fact that warm air rises and will escape from the upper part of a building, if cold air is admitted at the lower part. But if no openings are made below, the air remains stagnant, and cannot escape at the upper openings. In all arrangements for ventilation, these requirements must be met, and a neglect of them has often prevented the successful operation of costly, but faulty methods. In barns, a want of adequate ventilation encourages mildew, sweating and moulding of the contents, and in some cases over-heating, and spontaneous combustion of hay that has been stored in too moist a condition. The usual method of ventilating barns by means of one central cupola, or by a window in one or both gables, is dangerous,

Fig. 1.—VENTILATOR FOR BARN.

because it confines the escaping air, which is always charged with moisture in the summer time, to one considerable stream, and moist air, being an excellent conductor of electricity, serves to make the most dangerous lightning-rod—so to speak—to bring the lightning into the barn, and so set it on fire. This explains the cause of the frequent destruction of barns by lightning, during the season of harvest or soon after. It is wise, therefore, to break up the stream of air which escapes, both by having several ventilators, and to arrange these with slatted work on each side, to conduct the escaping air in downward or horizontal currents, which will spread laterally in a sheet rather than pass upward in a column. A useful ventilator for a barn is shown at figure 1. This is a tube of sufficient capacity, which starts at the ceiling or floor of the lower story, and passes through the upper one. If the upper part passes through hay or grain mows, it will be advisable to make several openings in the tube at that portion, that it may carry off any heat or moisture, which may exist in the hay or straw, soon after it is

Fig. 2.

Fig. 3.

Fig. 4.

put away in the barn. Where this form of ventilator is not suitable, others may be provided in the

eaves; one shown at figure 2, consists of a wooden frame, set in the wall near the ceiling or floor, in the manner of a window frame; the upper half of this frame is furnished with blind slats, so placed, as to facilitate an upward and outward current, the lower half has two sliding windows, or panels, which admit fresh air, while the foul hot air flows outward. This fresh, cool air drops down to the floor and makes a circuit, forcing out the foul air, and purifying the whole building. This arrangement has the advantage of distributing the fresh air, and more effectively, if the panels are fitted with slats set on end, and each half reversed, so as to force the air in different directions. Another ventilator, figure 3, set in the eaves of a stable, consists of a falling door, so hinged, that it closes of its own weight, and is opened by a cord arranged as shown in the engraving. The same kind of a side ventilator door may be held open by a piece of wire spring, figure 4, A, and closed by a cord, fastened at B. Another ventilator may be made by sawing out holes in the board, and pivoting on a cover with similar openings; this cover being moved by cords, to open or close the spaces. This ventilator, shown in figure 5, is one easily made and operated. The matter of thorough ventilation of barns and stables can not be too strongly insisted upon, as it determines in great measure the health and therefore the value of the stock contained in them. Pure air is as essential as pure food, and can only be secured to confined animals by a proper circulation through ventilators.

5.—WHEEL VENTILATOR.

### Among the Farmers.—No. 50.

BY ONE OF THEM.

One of my good neighbors met me at the store with a new pair of sheep shears. "Well," said I, "isn't that rather forcing the season, you don't shear sheep in January, do you?"—"No," said he, "but we use the shears to clip the horses' fetlocks. They are getting long now, and hard to keep clean. I always clip them about the time they are fully grown out. The horses look much neater for it."

### Grease ("Scratches") in Horses.

My friend's stable contains some ten or twelve work and road horses and colts, several of them of great excellence, and he has been almost every season more or less troubled with grease, or "scratches," as it is vulgarly called. No horses could have more attentive and careful grooming than his, and why he should have Grease in his stable I have, until now, been utterly at a loss to surmise.

Many years ago I read that the fetlocks constituted a protection to the skin on the pastern and above the heels, where it is especially sensitive, and as I had found that on horses deprived of this protection, that they might be more easily cleaned and kept clean in muddy weather, those parts often became red and irritated, if not drusy, I stopped the practice at once, and we have never since had chapped heels, or any trouble approaching Grease in our stable. Besides, I have taken some pains to inquire and observe, and have not yet found "scratches" originating in a stable where the fetlocks were left on, and where when the horses came in wet and muddy were simply rubbed off with a wisp or two of straw, and thoroughly cleaned with a good brush when dry.

Prevention is better than cure—and I think the sweeping assertions of the books that the disease is found only in neglected stables, and is always a disgrace, notoriously erroneous. Wrong care can just as well produce it as neglect.

### Road Taxes

are certainly a great burden in this country, consid-

ering how poor our roads are. We have town or district meetings, and vote money enough to keep the roads as they are—simply not dangerous—for a year—and we do well if some opposer of taxation does not lead off an opposition to any appropriation—and so we are content to take half or a third of the sum at first deemed desirable and necessary. We plunge through sloughs in winter, and rack our wagons in ruts, or creak through sand, and see no remedy. Year after year we are taxed, and though there are a few more roads, they are no better than they were a hundred years ago.

#### How Is It in the Old Countries?

They have been steadily improving. The possession of good roads is something rather recent over the greater part of Europe. It has come, for the most part, within 150 years; and that is since many of our roads were laid out in the Eastern States.

We have here no distinct classification of roads. A public road is distinguished from a private road, and from a right of way, but so far as custom goes there are no other distinctions except when turnpikes or plank roads are chartered. It would aid greatly if the State Legislatures would classify roads and establish certain as first class, and require that the townships through which they pass should keep them in such good order that the heaviest loaded wagons, or even artillery trains, would nowhere sink an inch deep in the mud. Roads once put in such order would require but a small annual outlay to keep them so, and the State ought to pay half the cost of making them at the outset. There is another class of thoroughfares which the county ought to aid the township in making, and which might differ from the first class roads only in the steeper grades and narrower road-bed. Highways of the third class should be just as good as the township could afford to make and keep in order.

Take the country around New York and the neighboring cities as a sample of the rest of the country, and it is clear that the market gardeners of the immediate vicinity have great advantages over those at the distance of ten miles, which would be of little moment if they had good roads over which at all seasons, and especially in the spring, they could trundle their heavy loads to market.

A few years ago farm products, potatoes, cabbages, squashes, apples, and garden vegetables, in their season, used to be transported from a large section of country about here in boats, or in wagons upon the hoats to New York. Then the railroads were built, and this class of merchandise was more rapidly and easily sent to town by rail. Now these same railroads bring this very class of goods from the western part of the State of New York, from Pennsylvania and Ohio, just about as cheaply as they will take our truck only 15 or 20 miles. It is therefore very important for the farmers and gardeners to have such roads to the neighboring cities as will make them independent of the indiscriminating rates of the railroads. There are thousands of acres of warm light land, well watered, early and easily worked, which, being within some 16 to 18 miles of the densest population of New York, might and would be used for raising vegetables if we only had better roads. This system of

#### Farmers Marketing their Own Produce

ought to be encouraged in every way by municipal authorities. The action of the New York authorities has been the reverse of encouraging to this kind of traffic. Whereas in Philadelphia, and many other cities, the people, or all who wished to do so, could buy every thing which the farmers and gardeners had to sell of the producers themselves, in New York, but little of that kind of trading could be done—and this little is beset with inconveniences—so that but few things could be sold in this way, potatoes, turnips, cabbages and green corn, tomatoes, carrots, peas and string beans, spinach and pot-herbs, with celery and horse-radish making up the list. Country-dressed meats, sausages, head-cheese, poultry, eggs, butter and pot-cheese, with the firmer fruits in their seasons, are rarely or never sold in New York by the producers. The result is had both for the citizens who buy and for the neighboring country folk who are the producers.

#### Draining at Houghton Farm.

Visiting Houghton Farm a few weeks after Dr. M. Miles had arrived and fairly settled down to work, I was delighted to find that the excellent system of laying tile drains, which he had inaugurated in Michigan, was here introduced and in full operation, with such improvements as his ever ripening experience would suggest.

There are two ideas which may take possession of those who undertake land drainage. One is that stones, brush, poles, boards, etc., which are sometimes used as substitutes for tiles, are really cheaper than tiles, and are even tolerably effective, and to be trusted for a considerable length of time. The other is that, aside from the proper surveyor's work, which is indeed very simple, there is great difficulty in getting the drains well leveled, and the tiles laid and covered without displacement. Any one who could have watched the operations of the ditch diggers, and tile-layers, as I saw them at work would I think be disabused of both of these ideas. The land where the men were at work was so nearly level that the fall appeared to be quite in the opposite direction to that which it really took. It is generally easy enough to lay the drains in land which has a considerable slope, but difficulties are encountered when there is but very slight fall. The drains in this case were staked out in eight-rod lengths or thereabouts, and dug out pretty nearly to the required depth, which was  $3\frac{1}{2}$  to 4 feet, according to the undulations of the surface.

Fig. 2.

Then, instead of using "boning rods" to determine the grade of the bottom of the ditch, a cord was stretched above the centre of the ditch, just high enough to clear the heads of the workmen. It was supported on "shears" (fig. 1) at each end, made by bolting together, five or six inches from their ends, two strips of wood like fence pickets, but of pine or some light wood. These strips are 6 feet long, and about  $2\frac{1}{2}$  to 3 inches wide, of  $\frac{3}{4}$  or 1 inch stuff. The ends are left square. A stout, light line, like a carpenter's chalk line, is stretched between these shears, which are placed straddle of ditch, one at each end of an eight rod length. To hold the shears firmly in place, the line is given one turn around one of the upper ends, and is then made fast to a stake driven into the ground ten or twelve feet away. It is important that the line should be taut, hence it must be light and strong. There will be a little sag in it, of course. This is practically taken out of it by means of "rests" placed at two or three points along the line. One of the rests is shown in fig. 2. A fork or rake handle, shod with a point of iron and capped with a short piece of gas pipe, having a movable arm 2 feet long, standing at right angles to it, and held in position by a wedge, completes the simple and efficient instrument. This is driven firmly into

Fig. 3.—SHEARS AND REST IN USE.

tween these shears, which are placed straddle of ditch, one at each end of an eight rod length. To hold the shears firmly in place, the line is given one turn around one of the upper ends, and is then made fast to a stake driven into the ground ten or twelve feet away. It is important that the line should be taut, hence it must be light and strong. There will be a little sag in it, of course. This is practically taken out of it by means of "rests" placed at two or three points along the line. One of the rests is shown in fig. 2. A fork or rake handle, shod with a point of iron and capped with a short piece of gas pipe, having a movable arm 2 feet long, standing at right angles to it, and held in position by a wedge, completes the simple and efficient instrument. This is driven firmly into

Fig. 1.—THE "SHEARS."

the ground near the ditch, and the end of the arm placed under the cord and raised just so as to take the sag out. In this case the line was set just 7 feet above the ditch bottom where the tiles were to rest, which placed it clear of the heads of the workmen. It is obvious that the adjustment of the line is exceedingly easy, as by spreading the legs of the shears it would be lowered, and by drawing them together it would be raised. Figure 3 shows the line above the ditch, supported by a single rest.

Two men were at work finishing a ditch and laying the tiles. One had a seven-foot rod, which was kept close by, and every now and then he tested his work and that of his companion by setting it on the bottom of the ditch and moving it under the line in a small arc. As the "finishing" of the ditch proceeded the tiles were laid. They were using inch and a half tiles with collars. The seven-foot gauge stick was notched to indicate the height of the tiles, and again to show the height of the top of the collars, so that placing the gauge stick in the ditch it would just clear the cord; placed upon the tile the line would lie in one notch, and placed upon the collar it would lie in the other.

This whole arrangement enabled the men to work with extraordinary rapidity. If moderately intel-

Fig. 4.—THE PUSHING SCOOP.

ligent and trusty, they can be left quite to themselves, and will do accurate and good work. Two men had, within two hours and a half, cleaned out four to six inches of the bottom of a ditch, and "finished" a bed for the tile, laid and covered them 8 inches deep, in one of the eight-rod lengths to within twenty feet more or less of the end. There

Fig. 5.—THE PULLING SCOOP.

were a good many stones in the bottom, too, which made "finishing" rather tedious. They had

#### Good Tools,

in fact, the best draining tools I ever saw.—The spades do not differ essentially from the common English draining spades, but are lighter and with D-handles. Two sizes only are used for digging, for 2, 3, 4, and 5-inch tiles. The blades are 17 inches long, the handles 28.

For finishing the ditches tools termed "finishing scoops" are generally used. These are both for pulling or pushing, figs. 4 and 5, and the blades are set upon long handles, by means of goose-necked sockets, by which the requisite angle is given to the scoop. The "Houghton Farm Scoop," figure 6, as I should call it, is similar to the others in the form of the blade, but the attachment to the handle is made at the middle of the scoop. (See illustration.) Thus the pull and push scoops are combined in one, a much stronger, lighter, and more efficient implement. The attach-

Fig. 6.—THE HOUGHTON FARM SCOOP.

ment being much stiffer, and the leverage between heel and point so much less, the angle at which the scoop is set is not nearly so likely to be changed by

any accidental strain or bending, which makes a great difference in the ease and rapidity with which work is done. I noticed scoops in use which had been altered from the common ones, by placing the

Fig. 1.—THE ECLIPSE WINDMILL AT WORK.

handle attachment in the middle, and others which were made of old saw-blades bent into the suitable form, and handled as described. The blade is preferably about 13 inches long, and the length of the handle, for all ordinary uses, only five feet instead of seven or eight, as they are commonly made.

There were some 20 men, I suppose, at work at this job of draining, and I certainly never saw such work go on more smoothly and rapidly, and at the same time so thoroughly well. It seems quite worth while to present the matter with some detail to the readers of the *American Agriculturist*. In ordinary underdraining, as done with boning rods on the usual plan, it is rare that the levelling is so accurate that there will not be a variation of more than half the diameter of tile, producing tendencies to fill up with silt, and frequently stoppages, after the drains have been in use only a few months.

When laid on Doct. Miles' plan, the superintendent has only to see that the lines are at the proper height, and well stretched, then the workmen will do all the rest, with hardly a chance of an error in the level or fall of more than the thickness of the wall of the tile itself, if even so much.

This is only one subject of many, with which I came away from Houghton Farm, well charged, and feeling as if I could say a considerable that would be of advantage to many of my fellow farmers.

### Improvement in Wind Engines.

The power of the wind is much greater than is generally suspected. If the air were visible it would be seen in motion very much like water, the current smoothly flowing when no obstructions interfered, but whirling, eddying, and irregular in its force, as obstacles to a free movement deflect

Fig. 2.—THE ECLIPSE OUT OF THE WIND.

the current into many directions. In making use of the wind as the cheapest available mechanical force the peculiarities of its motion must be taken into account. Air possesses weight, and in moving against a fixed object its momentum exerts a force just as much as if it was a solid body that

moved. The force exerted by the wind upon any stationary object is found by multiplying the square feet of surface opposed to the wind by the number of feet through which the wind moves in a second multiplied by itself, or squared and divided by .002288 or  $\frac{2288}{1,000,000}$ ; thus one of the 10-foot wind engines having 68 square feet of surface, in a wind moving 30 feet per second, or about 20 miles in an hour, which is what may be called a pleasant, brisk breeze, will receive a propelling force of 136 pounds, or more than equal to the amount of tractive force exerted by a horse moving at the rate of 3 miles in an hour. It is evident that the full utilization of this power of the wind depends very much upon the excellence of the machinery to which it is harnessed to do our work, so to speak; the more effective this may be, the greater amount of the

Fig. 3.—A MECHANICAL ATTACHMENT.

force of the wind is turned to useful account. It is quite as important to investigate this point in choosing a wind-engine as it is in selecting a water-wheel. In calling attention to several excellent wind-engines we merely remark that for most of the work of the farm, dairy, and household, and for many mechanical works, a wind-engine is the most useful, economical, simple, and safe power that can be employed. With proper self-regulating devices it will work steadily night and day, without feeding, without watching or other attention, needing only occasional oiling, to work on, while the owner sleeps, eats, or labors elsewhere. The engine is able to regulate itself, instinctively, as it were, to all the changes of the wind; turning out of the wind and stopping when it blows with excessive force, and turning in again and resuming work when the gale moderates. No other mechanical power can thus be left to regulate itself, except perhaps a water-wheel, and even this, in floods—which may be parallel in their effects to a gale—suspends its working. The Eclipse Windmill, made at Beloit, Wis., is the first that occurs to us. This made a wide reputation at the Centennial as the only mill there that was not damaged by the great storm of June 27th of that year. It is shown at work in figure 1, and out of the wind at figure 2. A side vane (shown at fig. 1) receives the force of a storm and turns the mill edgewise to the wind. When the force abates a weighted arm brings the front to the wind again. A remarkable mechanical device, shown at figure 3, is attached to this mill. It is one that changes an up and down movement to a rotary one. As the rod, A, moves up and down, the buttons, C, press on the inner rim of the

gear wheel and carry it round, one button working on the up stroke and the other on the down stroke, so that the wheel turns regularly and continuously.

Fig. 4.—A DOUBLE-HEADED MILL ON A BARN.

It is claimed that 120 revolutions per minute may be made in a 12-mile (an hour) wind. This enables the mill to churn, saw wood, run a lathe, cut and grind feed, etc., as easily as to pump water. The Challenge Windmill, made at Batavia, Ill., is a popular mill, and is both single and double. A double-headed mill, erected on the barn of the well known breeder of Hereford cattle, T. L. Miller, of Beecher, Ill., is shown in figure 4. This is a 30-foot mill, and cuts hay, shells and grinds corn, and pumps water for 300 cattle, 200 sheep, and 200 hogs; besides doing the grinding for the neighbors. The fine barn here shown is worthy of notice.

Figure 5 is the Myers' Windmill, a rosette wheel with rudder, made at Salem, Ohio. The self-regulating device of this wheel is peculiar. The vane is parallel with the wheel, and lies flat when the mill is in gear. When the force of the wind overbalances the weight, this throws up the vane, and the wind striking it, turns the wheel out of gear. When the wind abates, the vane is turned, and the wheel is brought into work again, as seen in the engraving.

At figure 6 is shown the Perkins' Mill, made at Mishawaka, Ind. This mill has been made since 1869, and is of the solid or rosette form; it is also a self-governor. Another solid or "rosette" mill is the "I. X. L.," made at Kalamazoo, Mich. (fig. 7). This is a self-governor, the wheel and rudder folding together in a wind too heavy to be safe. It is able to turn partly out of the wind and still run when the blow is not too heavy. Figure 8 is the Victor Mill, made at New London, Ohio, which is moved by broad sails, so fitted as to turn on pivots and regulate and equalize the motion as the wind

Fig. 5.—THE MYERS' WINDMILL.

may change. The regulating apparatus consists of the balls or weights seen in the engraving, which govern the position of the sails according to their velocity. The Stover Wind Engine, figure 9, made at Freeport, Ill., is a "rosette" mill with but three

joints and self-regulating, so that in a gale it turns itself edgewise to the wind and stops. A peculiar feed grinder, described in the *Am. Agriculturist* for Aug., 1879, is used with this mill. Its peculiarity is its light running power, being moved by very

Fig. 6.—THE PERKINS' MILL.

gentle winds. The Triumph Engine (fig. 10), made at Racine, Wis., is a recent invention, and has no vane; this regulates itself in a high wind by means of a governing weight, which folds the wheel and turns the edges of the sections to the wind when the velocity becomes too great to run in safety.

Each of the above mentioned engines is made by respectable and responsible manufacturers. Each one has special points of its own, which are described at length in the manufacturers pamphlets and circulars, and those who need such machines can use their own judgment as to which might suit their fancy or meet their necessities. For addresses of manufacturers, see business columns.

### Influence of Parent Upon Offspring.

Many and different views have been held upon the relative influence of parents upon their offspring; but in modern times, the discussions of this question date from the publication of a number of prize essays, written on the following subject: "Whether the breeds of live-stock connected with agriculture, be susceptible of the greatest improvement from the qualities conspicuous in the male, or from those conspicuous in the female parent." This was in 1825, and the prizes were given by the Highland Agri'l Society of Scotland; the essays, wholly, or in part, appearing in the Transactions of this old Society. The claims of one of these writers, can be briefly stated in his own words. "Any hypothesis which would assign a superiority, or set limits to the influence of either sex in the product of generation, is unsound, and inadmissible." This assertion seems bold, but we will see that even with 55 of the best years of thought and investigation in this direction, the essayist was not far from the truth as the matter stands to-day. Another writer asserts that the greatest modifying influence is possessed by the male, and gives a number of cases to prove his point. These instances cited by the essayist, admit of a different interpretation. Dr. Miles, in his "Stock Breeding," says on this point, "the males used being more highly bred

of like or similar characters are bred together, the stronger becomes the power of stamping those characters upon the offspring. When an animal thus bred, is crossed with one without any strong common characters in its ancestry, the former has the greater influence—the controlling power over the offspring. So far as known, this principle holds equally good with females as males, but as, in general practice, a blooded male is crossed with grade or "native" females, and the result is an animal more after the sire than the dam, it is quite natural that the conclusion of the writer might be obtained. The reason why, in the majority of cases, the males will be the higher bred, goes without saying, the whole question resting on the fact, that a male can serve a number of females. Through the purity of the blood of the males, must the mass of domestic animals be raised to a higher standard, and it is the work of the pure-blooded female, to produce these males to go out and infuse this higher blood; to impress good, strong characters, on the otherwise comparatively plastic natures of the low-bred stock, or in other words, those that have not been bred at all.

We must not confound strength of character, as we have been using the term character, with the vigor and strength of the animal. A male of high constitutional development, full of animal life, may be very weak as regards its power to impress itself upon the offspring, and *vice versa*. Aside from breeding, or the lack of it, there are other, though secondary conditions, which determine in some measure, the animal's prepotency. Thus, the age has an influence. Animals either immature, or in old age, do not, in general, control the offspring to the degree that is observed when in the full strength of middle life. Again, the powers may be lessened by over use, to be regained after a period of repose. It is hardly necessary to mention that in some of these secondary modifying conditions the sexes do not share equally, as is especially the case in the one last mentioned. Another of the Highland

Fig. 8.—THE VICTOR.

essayists dwelt upon the theory that the male controlled the *external*, and the female the *internal* qualities of the animal. This ingenious idea has been the one most discussed in later times; but being based on pure assumption to start with, and not upheld by subsequent physiological, or rather embryological, study, it, like many others, has the Scotch verdict upon it; "Not Proven." Dr. Miles, whose work, above mentioned, contains all the most recent information on this question, says: "Instead of a limitation of the influence of each parent to a particular set of organs, we find the parent that is prepotent in the transmission of its characters, has a controlling influence upon the internal as well as the external organization of the offspring." Whatever the whole truth of the subject may be, at present it must be admitted that there is only one known law bearing upon it, and that is, "Like produces like;" the action of which results in fixity of character, and therefore controlling power.

**Yeast as an Insect Destroyer.**—In a recent paper on "Destruction of Obnoxious Insects by Application of the Yeast Fungus," Dr. Hagan, Professor of Entomology in Harvard Uni-

versity, states some facts and experiments, and suggests a probable remedy for the injuries caused by insects. The statements of Doct. H. are of so much interest to the agricultural world, that we make an abstract of them. It is a well known fact,

Fig. 9.—THE STOVER ENGINE.

—and one that especially troubles house-keepers late in the fall—that the common house-fly dies of a fungus, a white mould, which after death often holds the insect to the ceiling, window, etc. This fact suggested that other insects might be killed by inducing a fungus, or mould, growth within them. Yeast is a fungus, very common, easily provided, rapid in its growth, and the one it would seem of all others to be used for such a purpose. The mode of application is to sprinkle the obnoxious insects and their food with diluted yeast. This is the theory; but is it a practical one? All questions like this must be settled by thorough experiments, and, as far as the present goes, only a few trials have been made. Dr. Hagan states that four experiments are on record, three without success, but the results of the fourth are more favorable. In this case Potato Beetles were selected as the subjects, and after being divided into two parcels, one of the groups was sprinkled with a yeast solution on three or four successive days—the eighth day the sprinkled parcel of bugs began to die. All were dead thirteen days after the first sprinkling. Of the other parcel, only three had died, and all the rest were alive and well a month later. There were about 50 in each parcel. Upon examination with the microscope the fungus was found in abundance throughout the interior of the yeast-fed Beetles. The author of the paper arrives at the following conclusion: "That the application of yeast on insects produces in them a fungus which becomes fatal to the insects." It is evident that a large number of, and more extended, experiments are demanded before the practical value of this method of extermination of injurious insects is known. "The sprinkling of potato plants infested with the Potato Beetle and by their larvæ is easy, certainly as easy as the use of Paris Green, but less costly.... The application on greenhouse pests is so easy that

Fig. 10.—THE TRIUMPH ENGINE.

I hope the remedy will prove to be a great benefit to horticulturists." The remedy is so simple that it deserves at least a wide and general trial, which might result in showing this suggestion to be a great boon to farmers and cultivators everywhere.

Fig. 7.—THE "I. X. L." MILL.

than the females, and therefore likely to be prepotent in the transmission of their qualities, his conclusions as to the superior influence of the male, are not sustained by the evidence presented." There is an important thought in this quotation. The "more highly bred," that is, the longer animals

### Stiernward's Swedish Churn.

In describing, last month, the separation of cream by centrifugal force, it was mentioned that the invention was originally a Swedish one, though the American application of the principle was entirely original. Another Swedish dairy utensil may be worthy of note. This is a rotary churn which, although not entirely novel in construction, has

Fig. 1.—STIERNWARD'S SWEDISH CHURN.

some points which are made much of in some recently made churns. It consists of a tin cylindrical receptacle, figure 2, *F*, provided with 3 wings inside, *e, e, e*, which are pierced with holes. The dasher consists of a central tubular axis, having 3

wings, *E*, that are pierced with holes. A small turbine, *T*, is fitted at the bottom of the axis, with which it is connected. The axis is provided with a pinion at the upper part, which connects with a gearing upon a shaft and crank fitted in a frame, furnishing the motive parts, figure 1. The operation of the churn is as follows: The cream is put in the churn, *F*, which is surrounded by a jacket in which hot or cold water may be placed to warm or cool it—it is churned by the revolving dasher, *E*. As this revolves, air is drawn down the tubular axis by the operation of the turbine, *T*, and is forced through the

Fig. 2.—THE CYLINDER.

cream, and is carried with it through the holes in the wings of the churn and the dasher, and serves to help, as it is claimed, in the production of the butter. The inventor claims that this churn will separate the butter directly from milk in quite as

short a time as when cream is used, and that the remaining milk is perfectly sweet, and can even be boiled without curdling. In the present search for novelties in dairying, this may offer some hints to the ingenious and tireless inventors of new churns.

### Draining a Wet Cellar.

There is frequent complaint of wet cellars. Several communications are now before us requesting advice as to preventing the entrance of water through the walls of cellars that are dug in rock or clay. Where surface water fills the soil it will penetrate a cellar wall unless means are provided to carry it off. The most simple method is that shown in the accompanying engraving. This is intended for those cases in which surface water enters the walls, being prevented from sinking by impervious clay or rock above the level of the bottom of the cellar. In these cases it is not necessary to drain lower than the top of the impervious stratum. The drain here shown is carried down to this stratum, and tiles, stones, or gravel are laid to carry off the water which is caught in the drain. The cellar wall is protected by a coat of cement, shown by the dark line; this is carried under the drain tile so as to cut off the flow of water and turn it into the channel. The trench should be filled with broken stone or gravel, so as to furnish an easy course for the surface water to sink to the tiles. In case water rises in the bottom of the cellar the drain should be dug at least a foot below the level of the floor. In choosing a site for a house much trouble may be avoided by examining the spot where it is proposed to place the foundation, and in digging for this, where water is present in the soil, or it may be expected, the excavation should

SECTION OF DRAIN.

Fig. 1.—PLAN OF ICE POND.

be large enough to allow the drains to be put in when the foundation is built. This will prevent all trouble and inconvenience that might arise.

### An Artificial Ice Pond.

The mild weather of the ice-making season renders any description of ice ponds somewhat tantalizing, but as an ice pond cannot be made in a day, nor in the winter, it is pertinent to describe anything new in this way, although there may be no ice. A novel idea in the way of ice ponds is communicated by Z. M. Jin, who, following our suggestion for a Water Collector, (Oct., 1879, p. 384), is making an

Fig. 2.—THE SWEEP.

Fig. 3.—A SECTION OF THE POND.

ice pond on a similar plan. At figure 1 is his plan of the pond, which is partly made by an embankment 4 feet high. The pond is 40 by 150 feet, which would

give 4,500 cubic feet, or about 150 tons, with a thickness of 9 inches of ice. A platform is built at one corner for loading the ice, and a derrick made in the fashion of the old well sweep, is fixed on the bank near by. The sweep is shown separately, with the tongs, at figure 2. At figure 3 is a section of the pond, showing the banks and the platform. It is intended to fill the pond with water by means of a pump, worked by a windmill situated near by.

### A Handy Corn Coverer.

Mr. Clarence Hollins, Todd Co., Ky., sends a sketch of a home-made implement which the farmers in his vicinity have been using for a number of years for covering corn, peas, beans, and other large seeds planted in rows. "It does the work nicely where the ground is mellow."—The runners, *A*, are of heavy wood (oak) to give weight, 3 feet long, 6 to 8 inches wide, and 4 inches thick. The front piece, *B*, is 20 inches long, and is raised an inch at the bottom, to allow the loose soil to pass under, while it throws the sods and stones out of the way. The back piece, *C*, is an inch lower on the bottom than the sides, so as to drag in the loose soil and fill up the furrow, leaving the seed well covered, and the soil level and smooth. The bar, *D*, binds the whole together; it has a hole in the center, to which the clevis for the whiffletree is attached. The standards, *E*, are fastened in place

A CHEAP CORN COVERER.

with large nails, and are of sufficient height to support the handles, *F*, by which the implement is easily guided.—Mr. H. having just completed a useful home-made affair from a drawing in the *American Agriculturist*, was impressed with a desire to return the favor, and sends the above, an example that we strongly commend to other farmers.

### Hints and Helps For Farmers.

**DRAINING SLOUGHS.**—An Iowa farmer has a slough in his farm, which prevents the working of the land in the spring, until it is too late to plant, and wants to know how to drain it effectively. This is but one case in hundreds, in which the same difficulty occurs. To remedy it is a simple matter. When the ground is dry, plow out the center of the swale, until as deep a trough as possible is opened; then plow back and forth in the center to

Fig. 1. DIRECTION OF TILE.

loosen the ground, shovel out the earth, and put one horse in the ditch with the plow to loosen the earth still more, until it is 2½ or 3 feet deep. Then make a smoothly graded trench with a spade, and if stone or coarse gravel is handy, fill the trench 2 feet deep, and as wide as may be convenient; or if no stone is at hand, lay 1 or 2-inch tile at the upper end, down to the fork of the swale, as shown in figure 1. There dig a sink or "sump," figure 2, to collect the water with any sediment that may be in it, and lay 2 or 3-inch tile from the sink to the outlet. Then cover the stone or gravel with the plow, and smooth the whole hollow down to the center from both sides;

Fig. 2.—THE SINK.

if tile is laid, this should be covered at first with soil carefully by hand, and trodden down. Afterwards the trench may be filled by the plow.

**TO COLD-SMOKE MEAT.**—Meat is injured in smoking by excessive heat. The smoke should be

Fig. 3.—ARRANGEMENT FOR COLD-SMOKE MEAT.

cold to produce the best effects. To make cold-smoke, a fire pit may be made 10 or 12 feet from the smoke-house, and two feet deep. A flue of stone, pipe, or tile, may be laid from the bottom of the house, to the bottom of the fire-pit, and one from the top of the fire-pit, to the floor of the house (fig. 3). When the fire is lighted, and the pit is well supplied with bright coals, it may be filled up with green hickory wood in small pieces, or chips, and the cover, a flat-stone, placed over it. The smoke will then be strongly charged with Pyroligneous Acid, and will be cool; this will give the best flavor, and the longest keeping qualities to the meat.

**HOW TO TAR HEMP OR A ROPE.**—A coil of rope or hemp yarn, may be tarred by the use of the contrivance here shown (fig. 4). It is a trough to hold hot tar, having a roller fixed on each edge at the sides, and one at the bottom. The rope is drawn from the coil through the tar, and upon a reel, as seen in the engraving. If too much tar is carried over, two rollers may be used on the side where the rope passes out, and the upper will press out the surplus tar, or a bunch of oakum may be fastened below the roller to wipe off the loose tar;

Fig. 4.—MACHINE TO TAR A ROPE.

but unless the tar is wasted, it will be well to let some extra go over the roller, as it will be absorbed by the rope on the reel. To tar a thick rope, it should be drawn over the two rollers, and as it passes, the tar may be brushed on with a coarse brush. The reel may be turned slowly, and the rope drawn from the coil placed at some distance, to give sufficient tension to the rope. With a machine like this, tarring a rope is rapid and easy.

**A HARNESS BENCH.**—A subscriber from Indiana, sends a sketch of a harness bench, with the following description. The bench is a common four-footed one, and serves for a seat. The clamp is made of two halves of a barrel stave, screwed firmly to the block which is fastened to the bench by a pin, that is made firm by putting in a wedge underneath the bench. The edges of the jaws are beveled so as to come together evenly, and take a firm hold of the leather. They are held together and pinched by means of a pin and small key, figure 5. The pin is slotted, and the key passing through the slot is wedge shaped, so that the jaws are tightened by

Fig. 5.—A HARNESS BENCH.

pressing the wedge down in the slot. The box in front, is for tools, thread, wire, rivets, etc., etc.

### Washing Dairy Pans.

There is much labor in washing milk pans, and as, in careless hands, this work is certain to be ill done, it is well to contrive some plan in which it can be done easily, and then it will be more likely to be well done. By using some simple contrivance, pans may be washed without handling them. Recently the writer, having occasion to show a hired man how to clean some dairy utensils, made use of a Whitman Fountain Pump, which threw a stream of water into the cans and pails with considerable force, and cleansed them perfectly in a very short time. This was done on the grass outside of the dairy-house, and the convenient method may be elaborated so as to make a most serviceable plan of washing, thus saving much labor. The first requisite is a rack to hold the pails and cans, sloping forward slightly, so that the water can be easily forced in and will run out readily. A rack, made as in figure 3, consisting of a shelf slightly sloping, supported by side pieces, and a foot-board, will answer the purpose. The pails and cans may be laid upon this shelf, a light cross-bar preventing them from slipping forward, and may be piled one upon another. A stream of water can be directed into them through a hose, either by the pump above mentioned, supplied from a pail, or by a hand-force pump, a Blunt's Universal pump, for instance, with which the water may be forced from a well at some distance. But the plan, once explained, can be easily modified or changed to suit any circum-

Fig. 1.

Fig. 2.

stances; the easy washing of the pans being readily understood. Another method is shown at figure 1. This consists of a stout standard supplied with galvanized iron rods, upon which the pails may be hung and washed. A very complete apparatus may be made by carrying a lead pipe, with branches and jets, to the mouth of each pail or can, and connecting the bottom of the pipe with a hose from the force pump. After the pans have been washed, they may be left to hang upon the stand to drain and air. A frame of a similar kind for the washing and airing of shallow pans, is shown at figure 2. This consists of a standard with double rods spreading so as to give a firm seat for an inverted pan, shown also at figure 4, with the pan reversed. These may all be used in the washing-room of a dairy house, made as it should be, with a cement floor sloping to a drain; or they may be fitted on a plank floor outside, so placed that the water will

Fig. 3.—RACK FOR WASHING PANS.

flow off on the grass, or into a channel which will take it where it may do the most good. The idea is given in its crude and partly developed condition, to be improved upon as may be possible by those who perceive its usefulness. It is certain that much may be done to simplify the laborious hand-washing, which is especially disagreeable in the winter time, and is always slow and sloppy work.

**Our Domestic Animals.**—To get an idea of the vastness of the interest of farm animals, we must look at the number this country possesses. Thus there are: Horses, 11,000,000; mules, 1,700,000; cattle, 32,000,000; sheep, 38,000,000; swine, 35,000,000. When figures are in the millions, as these all are, the idea of greatness is about the only one that is conveyed; but with that thoroughly in mind, the importance of farm animals is better understood, and their relation to our individual and national prosperity is much more easily comprehended.

Fig. 4.

### The Manufacture of Amber Cane Sugar

Attempts have been made for several years past to overcome the difficulties in securing the granu-

Fig. 1.—CRUSHING MILL.

lation of the sugar contained in the juice of the different varieties of sorghum grown for that purpose. The trouble has been that the juice in the process of boiling down produced molasses which possessed an inferior flavor, and from which a very small proportion of crystallized sugar could be obtained. About a year ago a number of western men, interested in this matter, formed themselves into the Mississippi Valley Cane-Growers Association for the purpose of making organized efforts to secure a more successful result. The members planted cane, and worked it up into sugar under some improved processes with unusual success; and sugar of excellent quality has been made in many of the Western States, from Texas to Minnesota. The variety of cane grown in most of these experiments has been a new one, a supposed cross or hybrid of the Chinese and African sorghums, and known as Early Amber Cane. This has the advantage of early maturity, and can be grown wherever corn succeeds; its earliness also enables the sugar-making to be carried on during warm weather, when the process of granulation is more

Fig. 2.—A BOILING PAN.

complete. Nearly all the sugar made the past season has been from this variety, and one lot of 45,000 pounds has been made by one party at Crystal Lake, Ill., and sold in the Chicago market. Of this

lot a sample was sent to us by Mr. I. A. Hedges, who is Secretary of the Association above mentioned. Mr. Hedges has been closely identified with the sorghum sugar interest for some years, and has recently published a small book on the

gravity to the boiling pans. This plan, however, contains the whole of the machinery, the engine is seen on the left, and the mill with feeding and discharging apron connected with it on the right. The discharging apron conveys the "begasse" or

cooler, *H*, and from this into barrels. If intended for sugaring, the syrup is more carefully worked and purified in this pan, and then run off into a granulating vat sunk in the ground under the pan or elsewhere, in which, after standing some time, the sugar separates, and the molasses is pumped off. For small works a finishing pan (fig. 2) designed by Mr. Hedges may be used. This can be emptied by tilting into a movable vat, from which the molasses may be removed, to granulate. After granulation the sugar is separated by draining in a vat or barrel, or is "swung" in a "centrifugal" (fig. 5) in a similar manner to that in which honey is freed from the comb. The process of sugar-making does not depend upon the use of any particular machinery, but upon certain mechanical and chemical operations, in which the water of the juice and any vegetable fibre, or other impurities contained in it, are removed, and from which the actual sugar is separated. Mr. Hooker, of Illinois, has succeeded in producing sugar in the following simple manner: A wooden, 2-roll, mill, fig. 6, a tub, and an evaporator, made on the same plan as that shown at figure 2. The juice (27 gallons) was poured into the boiler, and when the juice was warm a tablespoonful of soda was added; the scum was removed as it rose; when the juice was reduced to a thin syrup a tub of fresh juice was added, the soda was again used, and the skimming and boiling repeated; this process was continued

Fig. 3.—INTERIOR VIEW OF A STEAM SUGAR HOUSE.

subject, in which he gives details of what has been effected so far in producing sugar from sorghum.

It would appear that sugar of excellent quality may be made from Amber Cane wherever corn can be grown; the only question now to be solved is, can it be grown profitably. Profitably is a relative and not absolute term in this sense. A farmer may grow cane and make sugar for his own use profitably when he could not devote his sole attention

Fig. 4.—THE BOILING PANS.

to the business with profit; he may occupy his time and facilities that are not otherwise employed, and so in reality procure his sugar with but a very small outlay, just as one may make maple sugar at this season with profit by using time that would be otherwise idle. To know how this may be done is therefore a matter of interest to all farmers.

Amber Cane is grown and cultivated precisely the same as corn; the soil need not be in high condition to produce sugar; a fairly good, clean soil having lime in its composition, or being fertilized with 300 lbs. of gypsum per acre, is the most suitable. The crop is ready for gathering when the seed is hardening, or when almost fully ripe. The stalks are topped, stripped of leaves, and cut, bound in bundles, and set up in shocks until required for milling. The stalks are pressed in a mill having powerful rollers (fig. 1), and operated by horse or other power. The juice is gathered in tubs or a vat, from which it can be raised by a pump and poured into the filter, from which it passes to the boiling pans (fig. 4). The whole process of boiling, clearing, or defecating, and concentrating the juice, may be explained through the accompanying plan (fig. 3) of a sugar factory designed by Mr. Hedges and described by him in the book previously mentioned. The building is 60x40 feet on the ground and 20 feet to the eaves, and if it is practicable, at the foot of a bank, upon which the crushing mill may be placed, so that the juice may flow by

crushed stalks into the furnace beneath the boiler of the engine. The juice flows from the mill into a sunken tank under it, from which it is pumped into the elevated reservoir, *A*. From this it passes into temporary tanks, *B*, in which it is "neutralized" by the addition of cream of lime, by which the natural acidity of the juice is corrected and the solid impurities are caused to settle. The cleared juice is drawn by a pipe into the heater, *C*. This is 25 feet long, 3 feet wide, and 14 inches deep, made of sheet iron three-sixteenths of an inch thick. The heater slopes to one end to facilitate skimming, and is covered with lids, to encourage the boiling. The boiling juice is skimmed, and the scum is drawn off with a light scraper into a tank, *D*, at the upper end of the heater. The steam from the heater is carried off through a chimney of boards, *E*, passing through the roof. The juice passes through this pan in a steady stream through a pipe into a second one, *F*, made of sheet iron, enclosed for protection in a wooden tank. In this the juice is left to settle, and is drawn off into a third pan, parallel with it, *G*, in which it is again boiled with the addition of more cream of lime to neutralize acidity, or albuminous matter, such as the white of egg or blood, is added to cause the liquid to throw up in the form of scum all impurities contained in it. In the plan, this pan or defecator has a steam coil for heating. The scum from this pan is raked off into the spout at the upper end,

Fig. 5.—THE "CENTRIFUGAL."

from which it passes into a vat where it settles and separates, and from which the clear syrup is drawn off to be returned to the heaters. When sufficiently concentrated the syrup is drawn off into the

a third time, and the juice boiled down until sugar was found by the tests used in making maple sugar to be ready to granulate. The syrup was then run into a tank and set away in a warm place to granulate and separate. The sugar made in this way was of

Fig. 6.—A TWO-ROLL MILL.

good quality; but from defective neutralization the quantity was too small and the molasses was acid.

At Crystal Lake, Ill., the cane from 600 acres was used the past year. The crop was very light, the season being unfavorable and the growers inexperienced; much of the planting was not completed until June 20th. The yield was so satisfactory that preparations are making for an extensive business the coming season. In this instance the best sugar machinery was used, including a costly vacuum pan and the best practical and experienced sugar experts were employed. The parties consider that the question of the profitable manufacture of sugar from sorghum is settled, provided the growers produce the syrup, and experienced sugar-makers work it up into the final product with the proper machinery.

Fig. 7.—EVAPORATOR.

### The Sharpless Strawberry.

Among the berries of recent introduction, the *Sharpless* appears to have stood the test of last year's cultivation in a very satisfactory manner. It is certainly a remarkable plant in its foliage, the leaves on even very young plants being enormous. This fact must be borne in mind in planting it, as it must be given abundant room if one expects to grow large fruit. Some of the large varieties produce a few very large berries on a plant, but what is wanted, is large crops of large berries, and from what we have seen of the *Sharpless*, it looks as if it would not disappoint us in either the size of the berries, or the number of them. To judge of the value of a variety, one should see the fruit on the plants. A few selected berries from a large bed, give no idea of what was left behind. Mr. E. P. Roe gave us last year a photograph of the whole produce of a little vine, which had been set in his grounds at Cornwall-on-the-Hudson, only two months before the "crop" was taken from it, and we had an engraving made of the picture. Those unused to strawberries, may think it does not tell a very large story for the *Sharpless*, while strawberry-growers will see in it indications of a large yield, especially considering that this is from a recently set plant, that should not have borne anything. It shows the peculiar shape of the fruit, and also its tendency to irregular forms, a character less manifest on old, and well established plants. As to quality; while we do not rank it as the very best, it is remarkably good for a very large berry, and we do not think there will be any complaints on the score of excellence. We shall look in vain for the highest quality, joined to the largest size.

### The Fraxinella.

Sometimes old plants are much rarer than novelties, and such is the case with *Fraxinella*, which has been in cultivation for well nigh 300 years. The plant is a hardy perennial herb, belonging to the Rue Family, and is a native of Southern Europe. It has a large strong root, from which arise several

leaflets, and as they bear a resemblance to the leaves of the Ash-tree, the plant was called *Fraxinella*, the diminutive of *Fraxinus*, the botanical name of the Ash. The flowers terminate the stem in a large, spike-like cluster 8 inches or more long, consisting of flowers of the shape shown in the engraving; the pendent character of the fifth petal, and the peculiar curving of the conspicuous stamens and styles, give the flowers an air of quaintness quite peculiar. The petals are of a light purple or purplish-rose color, handsomely and distinctly veined with dark-red. There is a variety with pure white flowers, and the two kinds together make a pleasing contrast. The plant has a very strong odor, all parts, but especially the stalks to the flowers, being furnished with glands which secrete a volatile oil; this has an odor much like lemon, but when the plant is rubbed or bruised the scent is very strong, reminding one of turpentine, and to most persons not agreeable. A well known horticulturist once told us that could he have but one perennial flowering plant it would be *Fraxinella*, mentioning as a reason for selecting it, that, in addition to the beauty of its flowers, it possessed such an agreeable perfume. We rather agree with Old Parkinson, who in "The Garden of Pleasant Flowers" (1650), in describing the plant, says that the leaves, etc., "are of a strong scent, not so pleasing for the smell, as the flowers are beautiful to the sight." It is not strange that a plant with so marked an odor should have been employed in medicine, but as it has no superiority over a

host of other aromatics, it long ago passed out of use. Parkinson, already referred to, says of it: "It is held to be profitable against the stings of Serpents, against contagious and pestilential diseases, and in Epileptical diseases and other cold pains of the brains"—and much more besides. The plant is really a very stately and showy one, and while we would not, like the friend quoted, give it preference over all others, it would certainly be included in any choice collection of herbaceous perennial plants. Probably the chief reason that the plant is so seldom seen in our gardens is, that old seeds are of difficult germination, though scalding is said to help them. With recently ripened seeds we have found no difficulty. It may also be multiplied by dividing the large roots. The botanical name of the plant is *Dictamnus Fraxinella*, the first is an old Greek name for this or some other plant; the meaning of the other has already been given. We should not omit one striking peculiarity of the plant; in a hot day it gives off its aromatic oil in the form of a vapor, and so abundantly that it will burn. This is best seen in the dusk of a hot day; by applying a light near the lower part of the plant this vapor will burn with a sudden flash of flame two or three feet high. It does not appear to injure the plant at all, and the experiment is very

astonishing to those who have never seen it before. The formation of this volatile, aromatic oil is so rapid and abundant that a fire flash of its vapor

THE FRAXINELLA (*Dictamnus Fraxinella*).

can be easily obtained from the same bush for quite a number of evenings in succession.

### Fruit-Growers in Texas.

Should Texas in 10 years from now suddenly appear as the great fruit-growing State of the Union it would not surprise us. With great capabilities in a most wonderful variety of soil and climate, she has also a people who are taking advantage of these, and a vast deal in the way of tree planting and horticultural improvement is going on, of which the rest of the country does not hear. Some five years ago, the owner of the principal nursery in the Southern States told us that his largest customers were in Texas, and that the bulk of his stock went to that State. As a natural consequence societies are being formed for united effort in the promotion of fruit-culture and horticulture generally. The North Texas Pomological Society has monthly meetings at Denison, and has a membership of about 40 of the most active fruit-growers of Grayson and adjoining Counties. Its Secretary, T. V. Munson, Esq., sends us a sketch of the meeting on January 3d last, and, as some of the matters presented have a general interest, we present them to our readers. In Texas, as well as, if not more than, elsewhere, fruit-growing is at present largely

#### A Battle with Insects.

And this Society, appreciating this fact, proposes to act not only on the aggressive, but with a combined effort. One method will be to trap certain insects at night. The Secretary writes, that at this meeting "several styles of lamps were presented for the consideration of the Society, which will adopt the form considered best, and have enough made to supply the members, each

THE SHARPLESS STRAWBERRY.

stems about two feet high, though in rich soil, well established plants are sometimes three feet. The compound leaves consist of from 9 to 13 ovate

paying for his own. They are to be used in our vineyards and orchards at various times during the

Fig. 1.—AN INSECT LAMP.

summer, to destroy insects flying at night. We propose to cooperate in this matter, and thus more effectually abate the insect nuisance." [Mr. M. sends a sketch of a lamp, figure 1, which embodies the ideas shown in various samples, and something like this will be adopted.—Ed.]

"The trap consists of a small lamp (L), so constructed that wind will not blow it out, placed in the center of a broad shallow pan (P), to which the lamp is held from upsetting from wind, by three clamps. A double reflecting shade (S) of tin is to protect the lamp from rain, and check the flight of insects when attracted beneath it by the light, causing them to fall into the pan. An inch of water is kept in the pan, with a film of coal-oil (kerosene) on it, for the destruction of victims. The reflection of light from the oil will attract many insects directly into the large, shallow pan.

"An atomizer was also exhibited, which is designed to throw a fine spray of some offensive or poisonous solution, through the tops of trees, everywhere among the leaves, to drive out curculio and

Fig. 2.—THE ATOMIZER.

codlings, kill canker worms in fruit-trees, to spray the foliage of vines, cabbages, etc.; to drive out or kill 'thrip,' 'leaf-rollers,' 'plant-lice,' etc., using strong solutions of carbolic acid, coal-tar, tobacco, or Paris green. It will far more quickly and efficiently do the work, and with a great saving of materials and labor over the force-pump commonly used for such purposes. A can (C) holding the desired solution, has a slanting tube (T), which starts on the inside near the bottom, and passes out a short

distance near the edge of the top, with a small V shaped notch in side next to tube (P), which is soldered on top of can. This outer or top-tube tapering like a blow-pipe, has its small end just opposite the V shaped notch in tube (T), and about 1/4 inch back from it. When air is forced through the outer pipe (P), liquid is drawn up from bottom of cup (C) through the inner tube (T), and blown to the distance of several feet, forming a cloud of fine mist (S). By attaching a hose (H), a power-fan (F) with a hand-crank-wheel (W), and suitable frame-work (which is not shown) to be supported on the shoulders by a strap, a continuous stream of mist can be blown; and the cup (C) supported upon a staff (B) held in the hand can be elevated and applied anywhere in the top of a tree. A bellows could be used in place of the fan. A working model of this was shown before the Society at its last meeting by the writer."—To our correspondent's inquiry we reply that we have seen no such apparatus offered, patented or otherwise; the nearest approach to it is one in which a bellows carries the atomizer at the end of the nozzle.

### The Onion Smut.

A few localities in the Eastern States have long been known as the centers of the onion crop. In some of these, where the onion has been the chief crop for the last half century, the culture has, within a few years past, greatly diminished, and in some cases it has been altogether abandoned. This change is due to the appearance of a destructive pest in the form of a fungus known as the *Onion Smut*. This smut makes its appearance while the onions are quite small, and if they are not entirely destroyed, are of very little value. A careful examination of a diseased plant in the early stages of the smut, shows that the fungus consists of a multitude of small filaments, or threads, collected in knots and stringy masses within the substance of the onion leaves and bulbs. At a later period a vast multitude of dark particles are found; these are so fine that they can only be seen in a mass as a black, dusty powder. At this time the skin of the leaves becomes broken, usually in long, narrow lines, and this dust, which is really the spores of the fungus, are set free. Figure 1 shows a young onion plant with the ruptured skin, or epidermis of the base of the leaves and the black powder—the smut—seen in lines upon the surface. Under the microscope, each of the dusty particles resolves itself into a somewhat spherical body, upon the surface of which are numerous small projections. Two of these spores are shown in figs. 2 and 3. The Onion Smut belongs to a group, or division, of fungi better known to most farmers by the common representative, the Corn Smut. Unlike the *Rusts*, the smut fungus is not believed to pass in its development through distinct states or forms, upon widely separated plants, and, therefore, for its prevention we do not have to look outside of the onion plant. It is generally supposed that it has come from the wild onion, or garlic, and, therefore, in the extermination of all such wild plants in the region a remedy may be found. The spores of the smut being very small, may cling to the surface of the onion seed and be planted with the onions; it is, therefore, a precaution to soak the seed, that the water may remove the spores from their rough surface. When the smut has been allowed to perfect itself, the soil is more or less filled with the spores, and gives truth to the

expression among afflicted onion growers, that "the disease is in the ground." The question of ridding the soil of the onion smut resolves itself into simply this: "How kill the spores therein?" Manuring the land, and giving it the highest culture and continuing the growing of onions will not do it. It may be that by so doing the smut will not be very troublesome, simply because strong, healthy plants are better able to withstand its attacks. This is a law

Fig. 2.

Fig. 3.

which holds good with diseases in general: the better the health; the more vigorous the subject; the greater the vitality, the less disposed is the subject to disorders. But this is not the best way to treat the onion fields that have been smutted, because they are usually already under good culture. There seems to be but one way—cease growing onions on the land for a term of years sufficient to exhaust the vitality of the dormant smut spores in the soil. Grow other crops, and in the course of four or five years the smut spores will have died. At present the trouble is not widespread, and knowing the fatal nature of the pest, every precaution should be taken that its limits be not extended. Those buying and selling seed should bear this in mind, for a little care in not taking seed from a smutty locality, may make thousands, if not millions of dollars, difference in the great and growing onion interest of our country.

### Greens For Everybody.

The real value of all food is not to be judged by the amount of nutriment it contains. Many of the green vegetables we consume contain so little of actually nourishing matter, that if one were confined to a diet of them, he would soon starve, as the digestion could not extract from them enough to sustain life. Still, their utility as articles of food is not doubted, and the very general desire for them, especially in spring, when most persons have been long deprived of them, is sufficient evidence that they are needed, did not physiologists tell us that the salts they contain are required by the system. Many, especially farmers, depend upon various wild plants for their first greens. The boys are sent over the meadows for Dandelions, to the brook sides for "Cowslips," as the Marsh-marigold is improperly called in this country; besides these, Nettle, Dock, Poke, Milk-weed, and numerous other wild plants, are used as pot herbs. Indeed, almost any plant that has no unpleasant taste and no injurious properties, and will cook tender, appears to be used in some part of the country. It is rarely that a farmer raises anything to serve as greens, unless he may have kept his cabbages in a cellar, and has saved the stumps to set out in the spring to give a crop of sprouts, and very good indeed they are. The trouble about the wild supply of greens is the time it takes to gather them, and the uncertainty of finding them when wanted. Moreover, they are generally not so tender as the more rapidly grown products of the garden. There is, perhaps, no useful plant seen in farmers' gardens so seldom as Spinach. During the past mild winter there has been hardly a day that it has not been abundant in the city markets, and in a mild winter like the past it may be had almost daily on the farmer's table, while in ordinary winters he can have it whenever the snow is off and the ground thaws. For this early supply the sowing must be made in September, and it is well to "stick a pin" just here in the memory, to make a sowing. Our object at present is to urge a spring sowing. While the crop from this will not be so early it will be most acceptable, and vastly superior to any wild plant, and those who become accustomed to it now will be sure to prepare next fall for an early supply next spring. Sow the seed in the richest soil in the garden in drills 15 inches apart; as it is a hardy plant the seed may be sown as early as the soil can be worked. In two weeks make another sowing, and two other sowings at intervals of a fortnight will not come amiss; this will bring the latest sown into hot weather when it soon runs up to seed and other things take its place. When the largest leaves of the spring

Fig. 1.

sown are 2 or 3 inches long, pull or cut out for use where it is thickest, and what is left will grow all the more rapidly. Farmers who live near markets will find spinach a profitable crop, especially that which has been wintered, though the spring sown will pay fairly. In ordering seeds do not forget a paper of "Spinach Beet" and of "Improved Dandelion." The first named is to be sown like heets to give greens during the hot summer; by cutting the outer leaves for use, taking care not to destroy the central bud, it will give a continuous and abundant supply of most excellent greens. The dandelion is to give greens early next spring. It must make a season's growth to get strong roots; these are to be thinned, or better, transplanted to a foot apart, and next spring they will give an abundant supply of greens as much better than the wild plants as one can imagine. Try it!

### The Honey Locust Hedge.

Having described the Honey Locust last month, we now consider the method of making a hedge. One can start with the seeds, or purchase young trees from the nurseries. Of course it is cheapest, so far as outlay is concerned, to begin with seeds. If one can afford to buy the plants he will gain a year, or perhaps two, in making the hedge.

*Sowing the Seeds.*—In our only experience with them, the seeds had been kept all winter in the pods; they were taken from the pods and sown at once, coming up as readily as beans. Purchased seeds may have become too dry, and it will be safest to soak them by pouring on warm water and allowing them to remain in the water for about 24 hours. A seed-bed of good light soil should be prepared, and the seeds sown as if they were beans, dropping them about 3 inches apart in the drill. The rows, if to be worked by hand, may be 15 inches apart, and twice that distance if a horse cultivator is to be used. During the season the young trees are to be well cared for by working between the rows and pulling up the weeds that appear in the rows. If any plants are crowded by too thick sowing, thin them while quite young.

*Setting the Hedge.*—Usually the plants will be large enough when one-year-old, but if they have not made a strong growth they may be allowed to grow another year. Nurserymen furnish the plants at one or two years old as may be desired. The first thing to be done with the plants, whether home-raised or purchased, is to assort them according to size, making two or three sizes. The object of this is to secure uniformity in the hedge; if a small plant is set between two large ones, the larger plants will keep the advantage, and there will be a weak place in the hedge. Besides assorting, the plants must be prepared by trimming, cutting back the long tap-root, and shortening the tops by cutting off the main stem and larger branches about one-half. This is very important, the object being to make the plant branch near the ground, which it will not do if the tops are all left on. In these operations, do not expose the roots to the air more than is necessary. The line of the hedge should be well plowed, and harrowed, but no manure will be needed; it should be a well prepared bed about 4 feet wide, in the center of which the hedge is to be set. It is very important that the hedge be set straight, and this can be best secured by stretching a line as a guide in planting. The plants are to be set 8 inches apart, and may be put in with a dibble, a large trowel, or by opening a cut with the spade, whichever method the planter may be most familiar with. A proper hedge—thick at the bottom—can only be made in four or five years, and it must have each year a severe cutting back, which should begin the first fall, cutting the plants back to a height proportioned to their growth. But of this it is not our purpose to treat at present. To answer some inquirers, we may say that in localities where the Osage Orange is perfectly hardy, we should prefer it to Honey Locust, on account of its greater hearty if for no other reason; but there is a wide belt where it is uncertain, and still another where it will not endure the winters, and in these the Honey Locust is the most available of all hedge plants thus far tested. It has been objected

that the Honey Locust is not suited to hedge-making because it is naturally a large tree, and can not be dwarfed without injury. The objection is entirely without weight, as we know that it has been in successful use for over 30 years; besides the same applies to the Osage Orange which, when it has a chance, will grow to a tree 60 feet in height.

### Peas in Plenty.

"This is not a pea country," said an Englishman to us, and he was right, it is not in the sense that England is, where they can take picking after picking from the same vines. The hot sun that gives us our green corn and tomatoes, which English gardens cannot have, puts an end to our peas. But we can have them in abundance during their short season, and should have them in far greater plenty than we do. Farmers are apt to be content with two or three messes, and many find it too much trouble to grow them at all. One great obstacle to an abundance of peas, is the necessity for sticking or brushing them, but that, as we shall presently show, may be for the most part avoided. The great point with early peas is to start early; select a piece of light, dry soil, all the better if it slopes to the south, and just so soon as it can be worked, plow and harrow it, furrow out rows at least 6 inches deep, 3 feet apart for dwarfs, and 4 feet for the taller kinds. Then scatter a good supply of the best and finest manure in the furrow, and sow the peas upon the manure, if well rotted; if not, cover the manure with an inch or so of soil. Then by the use of the rake or hoe, cover to the depth of 3 inches. Some cover only an inch at first, and as the plants show themselves, gradually draw in the earth, until the seed is 4 or 5 inches deep; the deeper, the better the plants will stand hot weather.

*Varieties.*—One who looks at a catalogue, finds a puzzling list of names, and it may help him to know that for the earliest peas, there are several names for what is essentially one and the same pea. Those not familiar with the matter, should know that there are two kinds of peas, the round and the wrinkled, and that there is as much difference between them in quality, as between field corn and sweet corn. The earliest peas are round. The wrinkled peas, if wet weather comes after sowing, will rot in the ground. Then again, there are dwarf and tall sorts of both kinds; the dwarfs are a foot or less high, the others grow from 2 to 5 or more feet. It need hardly be said that the tall kinds produce more from the same land, as they have the most vine; though the dwarfs may be planted closer, they, so far as our experience goes, are not so satisfactory as the others. Great claims are made for some of the newer dwarfs, that we have not yet tried. For general use, "Daniel O'Rourke," and "Carter's First Crop," are the best very early. Then comes "Alpha," the earliest of all the wrinkled peas. For the main crop, no pea is better than "Champion of England," and probably none ever will be. This should not be sown until the ground is dry and warm, or the seed may rot. "Bishop's Long Pod" is intermediate between the early and "Champion," but a second sowing of "Alpha," a fortnight after the first, will do well for an intermediate crop.

*About Brushing.*—None of the market gardeners brush their peas, and while we would give brush or other support if practicable, as affording better crops, and easier picking, yet one should not go without peas because he cannot stick them. When the peas come up, the ground should be kept clean with the horse cultivator, or garden plow, and if any weeds come up in the rows, pull them out; when the peas are about 6 inches high, throw a furrow with a small plow towards them on each side. When they begin to fall over, turn them all to one side, and let them lie on the ground. Every two or three days, turn them over to the other side of the row, especially after a rain; this is done very rapidly by using a hoe-handle, or similar stick, running it under them, and turning over several feet of the row at once. The "Champion of England" should, if possible, have some kind of support, as that is longer in growing, is taller, and yields more pickings. If brush cannot be had, use cord or wire stretched between stout stakes or posts.

### Pop-Corn and Its Varieties.

For some reason there have been of late an unusual number of inquiries concerning Pop-Corn. These come in part from those who would cultivate it for their own use, and in part from those who, having an impression that it is especially profitable, would engage in its culture as a business operation. As to this aspect of its culture—its profit, it is difficult to get at statistics, but from the fact that there are some persons who raise it year after year as a regular crop, we infer that it pays somewhat better than ordinary corn. As with all articles of produce, the supply of which is not regular, the price varies a great deal, it being sometimes twice or three times as high as at others, and those who grow it regularly, by taking advantage of times of scarcity, may make it pay in the long run. As to its culture, it is scarcely different from that of ordinary corn, but being smaller, may be planted closer. A light, warm and dry soil, and some stimulating fertilizer give the best results. It is most frequently sown in drills, which are 30 inches apart, and the stalks 15 to 18 inches apart in the drill.

*The Varieties.*—There are but four recognized by dealers, though occasionally others are met with, but do not appear regularly in the market. The leading kinds are "Large Pop" (fig. 1), "Rice" (fig. 2), "Shaker" (fig. 3), and "Maynard" (fig. 4.)

The first and third are the same so far as the size and color of the kernel go, but the "Large Pop" has 10 rows and a longer ear, while the "Shaker" has usually but 8 rows. The "Maynard" is 16-rowed, with much smaller kernels, which are whiter, and of a pearly appearance.

The "Rice" corn has very sharp-pointed kernels, giving the ear a peculiar ridged appearance; the rows, usually more or less irregular, are about 16, but often break up and run into one another. The diagrams give the real as well as the comparative size of the kernels and ears. As to which of these is best, we are unable to say; more seems to depend upon the condition of the corn than upon the variety, and those who are in the pop-corn business, always test the samples and purchase that which suits them without regard to variety. In popping samples of each, we could see

Fig. 1.—"LARGE POP."

Fig. 2.—THE "RICE."

Fig. 3.—THE "SHAKER." Fig. 4.—"MAYNARD."

scarcely any difference in quality. The yield, with a good crop, is said to be about as many bushels of ears of pop-corn as the same land would produce in bushels of ordinary shelled corn. It is always sold in the ear, and by weight, the price varying from one cent up to three cents per pound, but occasionally, when there is a scarcity, the price is considerably higher. The crop is not one to be commended to those who are in a hurry for the returns from their labor, as it can not be sold until it has been kept several months, and it is all the better if it has been kept for a year. The ability to pop is not fully developed until the corn is thoroughly seasoned. The drying may be hastened by artificial means, as we have had corn pop well when kept in a warm room for only two months after harvesting.

## THE HOUSEHOLD.

For other Household Items see "Basket" pages.

### Monograms For Needle Work.

A mark of ownership upon any article of clothing is an important item when the garment is lost and it is desired to find the owner. Again, in sorting the clothing as it comes from the wash, a mark of some kind, easily found, but not too conspicuous, is a matter of practical value; in fact, there are sufficient reasons why all underclothing should bear its possessor's mark or name. There are very

Fig. 1.

many ways of marking clothing, from a single letter stamped or written upon the fabric, or a simple stitch of thread, to the most elaborate designs worked with great care and ingenuity. To those persons who have a fondness for fine needlework, the designing and working of monograms furnishes an agreeable occupation. Some monograms are given in the accompanying engravings, not expecting that they will be just the initials for many of the readers, but rather as samples to serve as a guide—to suggest how designs may be made and the work done. The chances are only one in several thousand that any given person's initials are as shown in figure 3. The size of the monogram, and the color and quality of the thread used in its construction, and other like matters, will depend upon the kind of garment, nature of fabric, and "last, but not least," the taste of the designer.

### A Burlesque Art Gallery.

At a fair for charitable purposes that the writer recently attended, one of its most popular and attractive features was an Art Gallery—an "annex" to the main show, as it would have been called in the Centennial year. There was just an even hundred "works of art" on exhibition, all going to

Fig. 2.

show the duplicity and flexibility of our language, and the ingenuity of the "artist." For example, when a "View of Paradise" is announced on the catalogue, one's thoughts turn to some grand sight of a celestial city, but what he really sees is only a pair of dice. There has been much excitement over contests in swimming during the past year, and to see one must, of course, be well worth the price of admission to the gallery. "The Swimming Match" had but an ordinary glass of water in which to swim, and we wonder how it will "go off" when it comes to the "rub." "A Bridal Scene" was soon in full view, and for the moment it reminded one of a harness shop. "The Skipper's Home,"—a snug little cottage by the sea as we had always been told, proved to be only an ordinary slice of a very ordinary cheese. "Sweet Sixteen" excited much interest among the young men present. They were shown a collection of four times four lumps of cut sugar. Several dead mice proved to be "A View of the Catskills." The "Maid of Orleans" is a person for whom our historial reading had given us a very high appreciation. She was here sweet in character, but not so white as more pulling would have made her. Of course the lass

was candy from (New) Orleans (Mo-lasses). It is said that one seldom sees "A Perfect Foot," but here was one with all the inches, halves, quarters, etc., marked upon it, and yet looking at it one would think such a foot was the common rule. It was with some surprise that we saw it was announced that there was an "Eclipse of the Sun," as the almanacs had not foretold it, besides it was evening, but this did not prevent a black cloth from obscuring the view of a copy of the "New York Sun." "The Great American Desert" was the title of the next picture presented to the view of the lovers of nature and art. This was art in the form of a Pie! One of the neatest thing was a new version of the old song, "Coming Through the Rye." Three little artificial mice with their heads just sticking out of a loaf of rye bread. A pumpkin shell with a five-cent, toy time keeper upon it had the high sounding title of "The Watch on the Rhine." The pile of hinges, screws, knobs, bolts, etc., were all "Things to Adore," and "A View of Boston," that home of wisdom, was presented in the central portion of a wheel, *The Hub*. "The Missing One" was a mystery to us until looking all around a large paste-board unit was seen above our head. We can by no means go through the whole list, but as this is the presidential year, we close with "The

Two Candidates." We did not make a choice, Dates being sufficiently sweet without being candied. These extracts from the catalogue of the Burlesque Art Gallery are given to afford a hint to those engaged in the management of fairs, etc. Such an exhibition, when well carried out, is capable of affording a vast amount of innocent amusement, and may be made to add essentially to the receipts with a very small outlay. It should be in the hands of those who have sufficient ingenuity to present a fresh lot of pictures, as many of the "old masters" have become badly worn by long use.

### Household Notes and Queries.

**THE MOTHS.**—A word in season, is the one that tells. This is not the month for moths, but it is getting so far along towards the time when the precautions should be used, that in giving them now, many will be saved the trouble of writing to ask what to do with their robes, furs, etc. As strange as it may seem, we meet with intelligent persons, who do not understand the changes in insect life—all should know that we have first the egg; then the larva—some kind of a caterpillar, maggot, or grub, something of the "worm" kind; this then goes into the pupa, or chrysalis state, remains quiet a while, then comes out as the perfect insect—either butterfly, moth, beetle, fly, or whatever its kind. In the clothes-moth it is the larva, the caterpillar, that does the mischief; its perfect form is popularly known as the "Moth Miller," and in due time will be seen flitting about the house. Now the trouble arises from allowing this parent-moth to deposit her eggs upon or in the fabric, which afterwards furnishes the food for the young "worms." Prevention is thus seen to be the most important remedy. Hence various things that are distasteful to the mother moth, and not in-

Fig. 3.

Fig. 4.

jurious to the furs, woollens, etc., are in frequent use to keep the moths away. Of such are Camphor Gum, Cedar Shavings, Pepper, Tobacco, etc., sprinkled on the fabrics. But the best and surest method is, to put the goods away in a place—a box, barrel, or even paper bag—where the moths cannot enter—and pack the goods in it before there is any chance for the eggs to be laid.

**HOUSEHOLD ACCOUNTS.**—There are reasons why the wife or house-keeper should keep an account book. In the first place it would furnish interesting information of the number of pounds of sugar, spice, flour, meat, etc., that a family of a certain size consumes. How many know anything definite about these things! Again, such a record would suggest changes in the living in one way or another, and furnish a basis for calculation of the requirements for the coming year. We knew of a lady who went so far as to keep an account of the number of extra meals which she furnished in a year; and when it was announced the family were greatly surprised. A household account is a startling revealer of facts. As a matter of family history, a record should be kept—of course, the dates of births and deaths will be given in the Record to be found in the family Bible, but there are other things that transpire in a family worthy of note.

**RENDERING BOOTS WATER PROOF.**—The snow and water of winter will get through the leather of most boots, and anything that will aid in making them impervious, is of importance. There are various compounds employed, one of the best and oldest of which is made thus: A pint of Linseed Oil and 4 ounces Powdered Rosin are melted together with 8 ounces of Tallow, if of mutton all the better. They should be melted over a slow fire, and as the mixture cools stir while it is hardening. This preparation is to be applied to the boots, melting it with a gentle heat, applying while still liquid, and rubbing it in before the fire.

**VACCINATION.**—It is proper for us to call the attention of parents to this important operation, which should be performed upon every child. Vaccination is a simple matter, quickly done, but nevertheless of such moment that it should be attended to at once, and thus ward off an attack of that dreadful disease—the small pox.

**BAKED PORK AND BEANS.**—A request comes from a Virginia house-keeper that we tell how the "Boston Baked Beans" that are sold in the stores are prepared." We have had no experience with store baked beans, and do not know just how they are cooked, but for the best way to cook Pork and Beans in the New England style (we never could see the propriety of the prefix of Boston) we may help her. Do not expect to find it in a Cook Book; there are as many ways as there are books, and neither of them *the way*—which is our way. Beans, some; Pork, a piece, and a pot or pan big enough to hold them are required. Pick over and wash the beans, cover them well with water, and let them soak all night, or longer. Place the beans in a pot or saucepan, cover with water, and heat slowly; when simmering shows an approach to boiling, pour and drain off the water; cover again with hot water and boil the beans slowly until done. The pork, selecting a rather lean piece, is to be boiled in a separate vessel, while the beans are boiling. When the beans are so soft that they crush readily between the fingers, place them in an iron or tin pan, or an earthen bean-pot; remove the rind from the pork; score the top of it both ways into half-inch squares, and press it into the beans, the top of it only exposed; put in the water in which the beans were boiled, more or less as they are wanted moist or dry; the quantity varying with the kind of beans, is to be learned only by experience—nearly to the surface of the beans will answer for a first trial; put into the oven and bake slowly, at least 5 hours—6, or more, will do no harm. Variations which may be tried: A tablespoonful or two of molasses put in the pan with the beans gives a fine color and a flavor liked by most persons. Sprinkle a little pepper with the beans. Ordinarily the upper layer of beans will be browned, and often hard and parched; to prevent this, place slices of raw potato over the beans, but

not on the pork. Leave out the pork altogether, salting, and putting in a tablespoonful or two of beef drippings. Variations *not* commended: Boiling the beans without first soaking; boiling them without changing the water; boiling the pork with the beans; baking the pork without first boiling; using the pork with the rind on. In the days of brick ovens the bean-pot was put in towards night, and taken out the next morning. Those were pork and beans! At the present day such can only be found where the bake-pan and wood fires prevail, or in lumber camps. In either place the beans and pork are put into the bake-pan, and this completely covered with coals and ashes. Taken out in the morning! Talk about "Boston Baked Beans!"

### The Uses of Apples.

However we may esteem other fruits, the apple is the main reliance in late winter or early spring, as there is little else in the way of fresh fruits. For cooking, no fruit is equal to the apple, which is susceptible of being served in a great variety of acceptable forms, some of which are here suggested.

**APPLE SAUCE** is the form in which the fruit most frequently appears. There is apple sauce, and apple sauce. To make the best, requires the best apples. Select high flavored fruit, such as the R. I. Greening, or Spitzenberg, pare, and slice in thick slices, and put, with the needed quantity of sugar, in a dish with a tight fitting cover. Some have a dish made for the purpose, but a tin pail with a good cover will answer. Set in a moderate oven, and allow it to stew slowly, until thoroughly done; good apples will need no water. Apple sauce so prepared, is far superior to that made in the usual way....Next in popularity to apple sauce is,

**APPLE PIE.**—Stewed apples half an inch thick, between two flabby crusts, is a caricature on apple pie. The apple pie is made with sliced raw apples, in a very deep plate, and as few plates are deep enough, the sliced apple should be heaped up in generous measure. It is a mistake to spoil good apples with much seasoning. Cloves and allspice overcome the natural flavor; a very little cinnamon, or minute bits of the dried peel of a sweet orange, develop it. In many families, sauce and pie end the changes, while they are really but the beginning of the list. What can be better for a dessert, than

**BAKED APPLES.**—Either sweet or sour? Many have a notion that sweet apples are the only kinds proper for baking. They are indeed excellent—when sour ones cannot be had.—But for the perfection of baked apples R. I. Greenings are required: Remove the centers with a "corer," fill the cavities with sugar, set in a baking dish with a little water, and bake rather briskly. Apples so treated, are better than most of us deserve; but if we add, as they are eaten, a liberal supply of Jersey cream!....It is but a step from apples to

**APPLE DUMPLINGS.**—That person is not to be envied, whose recollections of childhood does not include apple dumplings—"such as mother used to make." That kind will never be found again, but a fair approach to it may be hoped for. Her's were both boiled and baked, and we never could tell which were best. Isn't the making of the crust for boiled dumplings a lost art? Well, we can manage baked ones, and there is less risk of failure, and consequent danger to the digestion.—"Both kinds of sauce if you please."

**APPLE CUSTARD** is not to be omitted. Pare and core the apples, stew in very little water until tender; pour over them a custard made in the usual manner, and bake until the custard is done. House-keepers find it difficult to select a pudding-dish large enough for this.

**APPLE FRITTERS** are much liked by many; Rather large slices of apples are sprinkled with sugar and cinnamon, allowed to lay for an hour or so; they are then dipped in a batter of flour and eggs, and fried in an abundance of very hot fat; for these, a wire frying basket is very convenient. They are drained for a few minutes, and served hot. If for dessert, they are dusted with powdered sugar when served, but if, as many prefer them, to be eaten with meat, the sugar is omitted.

**BROWN BETTY.**—We gave this several months ago, and will only briefly repeat. All the clean bits and fragments of bread are dried crisp in the stove oven with the door open, then rolled, and bread-crumbs are always at hand. Sliced apples, bread-crumbs, sugar, cinnamon, and a deep pudding dish. A layer of apples, sugar, spice, crumbs; apples, sugar, spice, crumbs, and so on until the dish is full. Bake.

**PAN-DOWDY OR APPLE SLUMP.**—Since wood-fires and the old bake-pan or skillet, with a cover to hold coals on the top, went out of fashion and use, an "apple slump" has not been possible. An imitation is made in a deep pan, and baked in an oven, but it is only a baked apple pudding. Probably the real thing can still be found in the lumber camps, and in the few other localities where wood is the fuel, and the open fire-place has not given way to the stove. The apples are quartered; the bake-pan is lined at the sides with a crust; apples are put in, packed solidly, some spice is used, and sufficient molasses, or part sugar, and part molasses, to sweeten; a top crust is put on, gashed to let the steam escape; the pan is set on the coals, and the coals put on the cover. Eaten hot with butter! Who can ever forget it! The side crust baked before the juice came from the apples; it then became partly penetrated with syrup; the apples were done to a rich crimson mass. Talk about apple meringues, and such flummery—Here was richness!

### A Slipper Case.

Next to the comfort of slippers is the convenience of a place to put them when not in use. It, with some

A HANDY SLIPPER CASE.

persons, costs in trouble about all that the comfort is worth to find their slippers, they having been left where they were taken off, or thrown into a dark closet, to become buried beneath a host of other things. The engraving shows a case for holding slippers, light shoes, etc., that may be constructed of any heavy cloth and nailed to the inside of the closet door. A case thus made and located is always ready for use, always out of the way, and a great comfort to those who use it. As it takes but little time, skill, or money, to make such a handy receptacle, it is almost a wonder that there is not one in every house, not to say one on every closet door. Slippers are articles that are so apt to get astray unless they have a place, and always wanted when one is tired, that it is a pleasure to be able to put one's hands on them even in the dark; and all this may be gained by having a hanging case, like the one here given, and then using it.

**Selecting Wall Paper.**—It is getting the season of the year, when the house is to be cleaned, and very likely one or more of the rooms will need re-papering. The general aspect—feeling so to speak—of a room, depends so much upon the paper on its wall, that the work of selecting the paper is an important one. It is to some extent a matter of taste, but there are general rules of taste.

## BOYS & GIRLS' COLUMNS.

### The Doctor's Talks.

As boys in different parts of the country do not all have the same amusements, there may be some boys who will read this who have never amused themselves (and broken windows) by throwing stones with a sling. The way I used to make a sling was to get a piece of leather from an old boot-leg and cut it in the shape of a long oval—much like two eggs, with their large ends placed together, and about that size, or rather smaller. To each end of this leather, attach a strong twine or cord, two feet or more long. In one of these cords make a loop, and the sling is ready. To use it you need some smooth pebbles. Place the loop in one cord over the fingers of the right hand, bend the leather and place a stone in the center, hold both strings between the thumb and finger, and give the sling a rapid whirling motion. At just the right time, and when the sling is whirling rapidly, let go of the strings and off the stone will go to a great distance; the loop being around the fingers allows you to hold on to the sling. The skill consists in letting go the loose string just at the right time. When this is properly done the stone will be sent surprisingly far. As the sling was whirled with a rapid motion, the stone had a tendency to fly off, but it could not go while both strings were held, letting go one, off went the stone, the farther the more rapidly the sling was whirled. It is one of the laws of motion that a body moving in a curved or circular direction tends to go off in a straight line. The force which causes it to do this is called

Fig. 1.

**THE CENTRIFUGAL FORCE,** a word which means to fly from the center. In the sling, the stone has a tendency to fly off, but it is held by the leather and can not go until you let go of the string. When you attach a ball to a string and whirl it about your head, you know very well what will happen if the string breaks. Illustrations of Centrifugal Force are seen when you set a grindstone to turning so rapidly that the water will fly from the surface, or when a fast driver on a muddy road spatters you with the mud that flies from the wheels of his carriage by this same force. If you whirl a parasol as the boy in figure 1 is doing, the same force will cause the ribs to fly apart and get as far from the handle as possible. A most important application of Centrifugal Force is seen in

**THE GOVERNOR OF A STEAM-ENGINE,** the regular movement of the machinery being due to it. The manner in which this operates is shown by the little affair seen in figure 2, which is a round stick with two shorter sticks attached to it at one end by a bit of leather. If this be twirled in the fingers to give it a rapid rotating motion, the side pieces, or arms, will fly out, and if the motion is fast enough they will take a horizontal position. In the steam-engine the Governor consists of two rods with a heavy iron or brass ball at the end of each. They are so arranged that they will be moved by the motion of the engine, and are connected with a valve in the pipe, which supplies steam to the cylinder of the engine in such a manner that when they raise they will shut the valve and diminish the supply of steam, or if they fall below a certain point they will open it and give the engine more steam. When properly adjusted they will keep the engine at a steady, uniform speed. There are a

Fig. 2.

great many kinds of Governors in use, all having the revolving balls, but differ greatly in the manner in which the effect of their spreading by Centrifugal Force is applied to the machinery. You can illustrate another

**APPLICATION OF CENTRIFUGAL FORCE** by attaching cords to a cup or basin, as shown in figure 3. It will be safer to use a tin vessel for this. Having ar-

ranged the strings, which may be easily done by putting a short cord or a wire around the dish, and attaching the

Fig. 3.

Fig. 4.

other cords to that; fill the cup with water, twist the strings together as in figure 4; hold up the cup and watch what takes place. As the cup revolves by the untwisting of the strings, the water, following the law of centrifugal force, will try to get as far from the center as possible; it will at first become hollow on the surface, and so soon as the motion is swift enough will be thrown over the rims to such a distance that may make it pleasanter to

hang up the cup than to hold it. This tendency of water to fly off from bodies in motion is made use of in factories and bleacheries where they have large quantities of cloth and yarn to be dried; the wet materials are placed in a cylinder of wire gauze, which is made to revolve from 1,000 to 2,000 revolutions in a minute. In a very short time the water is all thrown out by centrifugal force, and the material is taken out quite dry. In a similar manner much of our HONEY IS EXTRACTED FROM COMBS.

The best bee hives now have movable frames in which the bees build their combs. When the bees have filled their cells with honey, the frames of comb are taken out of the hive, and the caps of the cells being first cut away, are placed in an "extractor," where they are rapidly whirled; the honey is thrown out by centrifugal force, and the combs are returned to the hive for the bees to fill again. The same principle is made use of in draining molasses from sugar. An express or freight train moving with great speed

#### ON THE CURVES OF A RAILROAD

has a tendency to fly off by centrifugal force, and you will notice that an accident from that cause is guarded against by placing the outer rail on such curves some inches higher than the inner one. The statement that a pail or other vessel filled with water may be placed upside down without any of the water running out, seems at first quite improbable. It can easily be done, provided it does not remain in that position too long. As a pail would be too large for a boy to manage, you can do better with a tin kettle, or better still, with an old fruit can. It will be an easy matter to fasten a bail to a fruit can and a stout cord to that. Then, by care, the can quite full of water may be

Fig. 6.

swung around so that the mouth will be directly downwards, as seen in figure 5, and not a drop will fall out. Success with this interesting experiment consists in PROPERLY STARTING AND STOPPING.

You should first swing it back and forth like a pendulum, increasing the oscillations until by a skillful movement you can get a rotary motion. In this, the centrifugal force has such a tendency to carry the water off in a straight line that it overcomes the attraction of gravitation. I have seen the action of centrifugal force on liquids illustrated very prettily with a glass globe, in which a small quantity of water was placed, and colored

dark-blue to make it more readily seen. This was attached to gearing, which would cause it to revolve rapidly, and it was very interesting to watch the movements of the water in the attempt to obey the centrifugal force and fly off, it of course being stopped by the glass. It gathered in a narrow band as far from the center as possible, and so long as the globe was in motion staid as a narrow band (fig. 6) against the glass. Some one has made a rather amusing calculation, which shows that if the earth revolved only 17 times faster than it does now, the centrifugal force would be sufficient to overcome the attraction of gravitation; if it went around on its axis in a little less than an hour and a half, instead of taking 24 hours, all movable things would fly off by centrifugal force, the water included; the seas would become dry, and the imagination can hardly picture the consequences. But it is hardly worth while to consider how things would be if they were not as they are. Such calculations do but little good. I doubt if it will make one happier or better to know that had the builders of the tower of Babel only carried their structure to the height of 24,000

not—comes out as clear as daylight to your own delight.

The same principle of optics (as this branch of science which treats of light and eye-sight is called) is shown in various other ways; one of the most common methods consists in taking a card, with a cage drawn on one side

Fig. 1.—THE BRISTOL-BOARD PATTERN.

Fig. 2.—THE WHIRLING PUZZLE FINISHED AND BEING WHIRLED.

miles, the stones, or bricks, at the top would have all gone flying off by centrifugal force. THE DOCTOR.

#### A Whirling Puzzle.

Perhaps you have done it many a time; if not, try it. Take a dry pine stick, and light one end of it; let it burn for a few minutes, blow out the flame, and a live coal will remain. Now hold this stick by the cool end, and move the other rapidly around in a circle; a bright ring of light is produced. This is due to the fact that the impression of the object upon the eye is not instantaneous, but remains for one-third of a second. During the short time of a third of a second the coal has passed through a considerable space, and therefore the

Fig. 3.—THE BIRD IN THE CAGE.

impressions in all its different positions are received and become blended into a line of light. This duration of the impression which an object makes has made many tricks, etc., possible, some of which are very puzzling until understood. Figure 1 represents a piece of Bristol board, upon which two rows of peculiar looking figures are worked in yarn. The pasteboard is afterwards folded lengthwise through the middle, so that the lines come upon the center of each side, facing outward. A string is then attached at the middle of each end, and with a binding to secure the two halves the puzzle is complete. When seen for the first time the *Thaumatrope* is an object entirely without meaning. It may be handed to a guest, with the request to read the inscription, as it was to the writer. The more it is turned this way and that way, the more puzzled and bewildered one becomes, until

Fig. 4.—THE HORSE.

the strings at the ends are caught up and the thing is set in a whirl, when the reading—motto, request, or what

and a bird on the other, and strings attached as shown in figure 3. The trick being to put the bird in the cage. Again, a horse is put on one side of the card in a galloping attitude, figure 4, and the rider on the other, figure 5, when by whirling, as in the other cases, the two objects appear together as one picture, figure 6, because, as the juggler would say, "the hand is quicker than the eye."

As such puzzles are both curious and instructive, they are worthy of a little time in construction from the youngsters. It is not one of those things that only the ingenious can make, but is within the reach of any one who can find a piece of pasteboard and the picture of a horse, a boy to put on it, and a couple of short pieces of string. The more elaborate design, given in figures 1 and 2, is for the older of the girls, which they can easily make.

#### Our Puzzle-Box.

##### SCATTERED SQUARE.

(Find the first word [and initials] scattered in the first line of the following verse; the second word in the second line; the third word in the third line, and the fourth word in the fourth line.)

We love to play where brooklets run,  
And violets open to the sun;  
We love along the lanes to stray,  
And cull the flowers by the way.

##### METAGRAM.

From a word of six letters, make all the words necessary to fill the following blanks. (Example.—Fill the following blanks from a word of five letters. Father—me eat my—and then go to—. The word is *bread* or *debar*, from which you may get *bade*, *bread* and *bed* with which to fill the blanks.) I— the other evening I saw— run across the floor. He had a piece of— in his mouth. I could do nothing but—at him; but— chased him down to the—on the—of the house. We are considered a pretty—of folks, but it was a dark night, not a—to be seen; and although—"put on—" and ran at a pretty good—, the—escaped.

Fig. 5.—THE BOY.

##### CHARADE.

My first is rather personal,  
Yourself it may be reckoned,  
And thousands of my whole 'twould take  
Ever to count my second.

A. S.

##### CROSS-WORD.

My first is in number but not in one,  
My next is in planet but not in sun,  
My third is in mischief but not in play,  
My fourth is in morning but not in day,  
My fifth is in order but not in rule,  
My sixth is in student but not in school,  
My seventh is in sofa but not in bed,  
My eighth is in scarlet but not in red,  
My ninth is in shriek but not in yell,  
My tenth is in prison but not in cell,  
My eleventh is in onion but not in beet,  
My twelfth is in mutton but not in meat,  
My thirteenth is in wisdom but not in mind:  
My whole is advice of an excellent kind.

BIBLICAL ENIGMA.

The whole, composed of forty letters, is good advice, from a good book.  
The 1, 17, 13, 31, 6, 37, 24, 40, was a famous well, near Gerar.  
The 11, 18, 8, 27, 21, 10, 6, 2, is a place where clothing is kept.  
The 15, 29, 1, 7, 9, 22, 38, 30, was a Governor of Syria.  
The 13, 3, 26, 12, 34, 36, 30, 19, was a precious stone in the high-priest's breast-plate.  
The 30, 35, 15, 28, 5, 20, 8, 4, is a tree, common in Palestine.  
The 32, 10, 38, 23, 33, 28, 2, 9, is a spring of water.  
The 39, 25, 14, 18, 12, 22, 16, 23, was a city of Asia Minor.

Fig. 6.—THE BOY ON THE HORSE.

ANAGRAMS.

- 1. Light may cool.
- 2. For tin pieces.
- 3. Dire ration.
- 4. Ice funnels.
- 5. But a last sin.
- 6. Tea-urn fount.
- 7. E'en singer.
- 8. O! I bit Missie's lip.
- 9. Brighten any.
- 10. Fool's crime.

SYNCOPIATIONS.

Five letters show, if placed aright,  
What many a horse does in the light;  
Abstract one letter, and you've got  
A bond of union, break it not.  
Again a letter take and see  
A liquid used by you and me.  
Once more, and if the lady's that,  
Pray make your call, take off your hat.

CONCEALED ARTICLES WHICH MAY BE FOUND ON A FARM.

- 1. Give me a token, Nellie, by which to remember you.
- 2. George, has Pa decided to buy the mare?
- 3. The horse has lost a shoe.
- 4. Get Peter a key for his trunk.
- 5. The buds are swelling in the sunshine.
- 6. This hovel might as well be torn down.
- 7. Pa, I like maple sugar.
- 8. Ben, Charlie wants you.
- 9. John's tools are in the woodshed.

TRANSPOSITIONS.

(Fill the second blank with the same word which fills the first blank, transposed.)

- 1. I asked the—to—a piece off of one of his loaves.
- 2. My—could not—the temptation.
- 3. He won the—but he was—for life.

DOUBLE ACROSTIC.

- The finals form the definition of the initials.
- 1. An edifice.
- 2. Dark.
- 3. A town in Enrope.
- 4. Part of a shield.
- 5. A director.
- 6. A European town.
- 7. A lake.
- 8. Small.

DROP-LETTER WORDS.

- 1. —m—r—s—n—e—t.
- 2. —a—c—o—e—t.
- 3. —o—s—e—n—t—o—.
- 4. —i—c—m—t—n—c.
- 5. —a—d—c—p—s.
- 6. —n—o—g—n—a—.

WORDS ENIGMATICALLY EXPRESSED.

(Example.—Man-of-war in a hurricane. *Nightingale* [Knight-in-gale].)

- 1. Cut our hair.
- 2. Part noun.
- 3. A remote article.
- 4. Benevolent color.
- 5. Furnish a century.
- 6. A number of grandees.

No. 474 Illustrated Rebus.—Something all persons ought, and may here study, to know.

BLANK ANAGRAMS.

(Transpose the italicised words in a sentence, into one word with which to fill the blank in the same sentence, and complete the sense. Example.—I want a cup of tea, and *Emily made it*—[immediately].)

- 1. Our—had to cross a bridge.
- 2. *Mamie's Ruth* suffers with—.
- 3. *Artim nut oil* was used as an—.
- 4. *Old Gartia* was a Roman—.
- 5. *More shapes, Tom?* Well, I never saw such—.
- 6. *O! more bustle!* How very—.
- 7. *Even men* do sometimes speak with—tongues.
- 8. When we *got there* we found them—.

NUMERICAL ENIGMA.

I am composed of 10 letters:

- My 3, 4, is a pronoun.
- My 5, 9, 6, is another.
- My 5, 1, 2, 7, is an animal.
- My 6, 1, 8, 10, 5, is a very important household article.
- My whole is a very useful study.

B. F. O.

ANSWERS TO PUZZLES IN THE JANUARY NUMBER.

ADDED HEADS.—1. Imp—grimp 2. Rove—grove. 3. Edge—hedge. 4. Aul—bawl 5. Ear—bear. 6. Race—Graece.

STOREKEEPER'S PUZZLE.—PAY UP; first and last letter P, P (peas); 2d letter A (anaconda), 3d letter Y (Your initial); 4th letter U (U. S. Grant).

DOUBLE ACROSTIC.

Napoleon—Waterloo.

- N—arro —W
- A—hoon —A
- P—enobse —T
- O—b —E
- L—ancaste —R
- E—scuria —L
- O—rhoc —O
- N—ew Mex —O

CONCEALED BIRDS.—1. Linnet. 2. Wren. 3. Dove. 4. He'ron. 5. Kite. 6. Owl. 7. Hen. 8. Crow. 9. Thrush.

ANAGRAMS.—1. Beforehand. 2. Subordinates. 3. Intemperance. 4. Biographical. 5. Inoffensive. 6. Incidental. 7. Deficient. 8. Obstacles. 9. Bituminous. 10. Cylindrical.

P1.—He who minds not his own business, is not fit to be trusted with other people's.

ALPHABETICAL ARITHMETIC.—(7208)5631904(781). (Key.—Profitable.)

BIBLICAL NUMERICAL ENIGMA.—And let us not be weary in well doing.

The Pile of Winter Wood that was given in the January number proved to be of even greater interest to the young people than we anticipated. Answers from a number of boys and girls have been received with the correct and entire list. For the benefit of those who may have had some trouble, we give the list of woods in the pile. (1) Locust, (2) Fir, (3) Hemlock, (4) Elm, (5) Dogwood, (6) Beech, (7) Pine, (8) Willow, (9) Basswood, (10) Scrub-oak, (11) Birch, (12) Buckeye, (13) Cypress, (14) Walnut, (15) Maple, (16) Chestnut. With the list before you it will not be difficult to select the picture that represents each one of the kinds of wood mentioned above.

Answer to the Bean Puzzle.—The accompanying engraving makes the matter plain to all those who had trouble in putting in the four extra beans, and yet not increase the number of rows or number in each row. It will be observed, by referring to the January number, that there were two beans at each corner, while here there is only one. The corner beans are counted twice, and by removing one from each corner to the middle the count stands five for each row and allows an extra bean to be put in with the three already in the middle to make the six; the requirements of the problem are met, and what was once puzzling is now all clear.

This Is Leap Year—Why?

When the number of the year is divisible by four it is Leap Year, and such is the case with 1880. Just about the time, this, the March, number of the *American Agriculturist* reaches its readers, perhaps while thousands of boys and girls are looking over its pages, and even reading this very article, it will be the 29th of February—the Leap Year Day, that comes only once in four years. Nearly a year ago we saw a little girl then about three years old who had never had an anniversary of her birthday; but this year she will have one, and we hope it will be big enough to make up for all the misfortunes of being born on the 29th of the shortest month of the year.

"Leap Year," we have been told, "is an odd year;" but it has just been shown that it is altogether even. Why is it odd? we may ask, and the reply comes, "It is the year when the boys are girls and the girls are boys, and everything is turned around." O! yes, we begin to see! They have "leap year parties," and "leap year rides," and "leap year this and that," and the girls do the inviting, and driving, and managing, and many of the "company" things which the boys claim for their own on other and ordinary years. It is said that such matters are sometimes even carried so far that the young lady proposes to the young gentleman of her choice, and he has the privilege of accepting or refusing as he sees fit. Well! we will admit it is an odd year, though it is even all the same. But why do we have leap years? There must be some good reason for adding one day to every fourth year as it comes around to us. What is it?

The earth moves around the sun once a year, as you all have learned from your geography. The time required for the earth to pass around and return to the place from which it started is called a solar or sun year—the year made by the heavenly bodies. In olden times, men did not know that the earth moved around the sun. If there was any moving it was done by the sun they thought;

Fig. 1.—SLIDING.—(See next page.)

and it did seem to move. To this day we all say the sun rises and sets. Knowing so little about the revolution of the earth, it was very hard for men to arrange the divisions of time so that they would correspond with the solar year. The civil year is the one made by man, and, like many human things, it was at first very imperfect—that is, the civil year and solar year did not correspond very closely. In the time of Julius Cæsar, the two kinds of years had got so out of place that the spring of the civil year came in midsummer. To use an illustration, we will have two cog wheels that work into each other. If both wheels are in all respects alike, the same places will always come together at each revolution; but suppose one wheel is a trifle smaller than the other, the wheel representing the civil year smaller than the one of the solar year, then any points once together will keep getting farther apart. This was just the trouble between man's year and the natural year. Cæsar rearranged the civil year in 46 Before Christ, and introduced the system of having three years of 365 days and then one of 366—the additional day being given to February. The solar year is 365 days, 5 hours, 48 minutes and 49½ seconds, so that Cæsar's year of 365½ days, averaging the four, is about 11 minutes too long. The point is to get these two years; the year of the heavens which we can not alter, and the year of the almanacs to agree. Matters went on as they had been started by Julius Cæsar, with a loss of 11 minutes a year until 1582, over sixteen hundred years, when it became evident that the little yearly loss was too great and must be remedied. How could this be done was the question. At this time a Pope took the matter up—it was a time when Popes had great temporal power—and decreed that the fifth of October be called the 15th, and all the intervening days to be cancelled. This only set matters right for the time being, but the same Pope, Gregory XIII, made it a rule that the century years not divisible by eight be not leap years. Thus 1700, 1800, and 1900 are not leap years, according to the new rule. This omits three leap years in every 400 years. With this arrangement the civil and solar years almost coincide,

Fig. 2.—THE ROUNDED BOARD.—(See next page.)

the solar, exceeding by only 22½ seconds, or a day in about 4,000 years—a matter too small to need attention. Those who have followed us through, and we fear it has been rather dry for the younger readers, will see that it has been quite a hard matter to bring things around straight. The leap year comes from the fact that there is a fraction of a day in the solar year which it would not be convenient to have in the civil, so we put enough of the fractions together to make a day and have the extra one on the leap year, which comes every fourth year.

### Alum in Our Bread.

*A Chemical Examination of Baking Powders and its Results—The Use of Alum and its Deleterious Effects—Opinions of Medical Experts—Prompt Action of the New York and Brooklyn Boards of Health, etc.*

The *N. Y. Evening Post* has been giving this subject some attention, and has published the result of some remarkable investigations, which are worthy the close attention of thoughtful people. From its recent exposure of the use of *burnt alum* in some brands of baking powders, in place of cream of tartar, the following extracts are mainly taken:—Pursuing the investigation of the quality of the food sold in this city, the representative of the *Evening Post* took up baking powder as one of the articles in most general use in our households. It is used by nearly every family in the city, and it is naturally of great importance to those who eat the food made with it to know whether it contains anything injurious to health.

There are certain constituents of good baking powder which may be regarded as entirely free from danger. They consist of pure grape cream of tartar, bicarbonate of soda, and carbonate of ammonia. The cream of tartar unites with the other two ingredients, and carbonic acid gas is thrown off, producing the same effect as yeast in a much shorter time. It has been found, however, that alum will also unite with the other two articles, and carbonic acid gas will be produced. As alum costs less than three cents, while cream of tartar costs more than thirty cents a pound, it is easy to see why alum is substituted for the latter by some baking powder manufacturers.

The *Evening Post's* representative obtained the following expressions of opinion as to its effect when alum is used in baking powder, from some physicians of New York of the highest reputation and ability: Dr. William A. Hammond, formerly Surgeon-General United States, of No. 43 West Fifty-fourth street, expressed himself as perfectly certain of the injurious effects of alum, whether used alone to whiten bread, or as an adulterant of baking powder. "The hydrate of alumina," Dr. Hammond said, "would certainly be injurious to the mucous membrane. It would inevitably tend to constipate the bowels and interfere with digestion; and anything that tends to render the albumen of the bread insoluble, and therefore takes away from its nutritive value, is injurious."

Dr. Sayre, former President of the Board of Health, said to one of the representatives of the New York press: "After the experiments in this line by Liebig and other distinguished chemists, and vivisections with alum on cats, dogs, and other animals, with the published results, we may well ask what is the use of such experiments if we do not apply them to practice in the preservation of human life and health? The Board of Health should see to this." Dr. Waller, Chemist for the New York Board of Health, when asked by a *Sun* reporter as to the injurious effects of alum, replied: "You know what the effect of alum is when you take some of it in your mouth; well, that is just the effect it has upon the coats of the stomach."—The analysis of the various baking powders, as officially reported by the Brooklyn Board, reveals only two brands containing alum being sold in that city—Patapsco and Dooley's. As to the cream of tartar powders, the same report mentions the Royal Baking Powder as free from alum or any other injurious substance. There are probably more than five hundred kinds of baking powder manufactured in this country. Through Dr. Henry A. Mott, the well-known chemist, one of the most competent, trustworthy, and careful experts of this country, the following analyses were obtained, showing the presence of alum in large quantities in many of the baking powders having a wide sale. Dr. Mott kindly furnished not only the results of his own analyses, but also those of several chemists of high professional standing, including Professor Henry Morton, President Stevens Institute of Technology; Professor R. W. Schedler; Dr. Stillwell, analytical chemist, this city.

Dr. Mott's report is as follows:

*Dear Sir:*—In accordance with your request, I herewith embody the results of the analysis of baking powders procured during the past three months, in all of which alum was found as an ingredient:

"PATAPSCO,"	Contains Alum
(Smith, Hanway & Co., Baltimore, Md.)	
"DOOLEY'S,"	Contains Alum
(Dooley & Brother, New York.)	
"CHARM,"	Contains Alum
(Rohrer, Christian & Co., St. Louis.)	
ANDREWS' "REGAL,"	Contains Alum
(C. E. Andrews & Co., Milwaukee.)	
"QUEEN,"	Contains Alum
(Bennett & Sloan, New Haven, Ct.)	
"VIENNA,"	Contains Alum
(Church & Co., New York City.)	
"ORIENT,"	Contains Alum
(Crouse, Walworth & Co., Syracuse, N. Y.)	
"AMAZON,"	Contains Alum
(Erskine & Erskine, Louisville, Ky.)	
"GILLET'S,"	Contains Alum
(Gillet, McCulloch & Co., Chicago.)	

"TWIN SISTERS,"	Contains Alum
(Union Chemical Works, Chicago, Ill.)	
"INVINCIBLE,"	Contains Alum
(Snyder Brothers & Co., Cincinnati.)	
"KING,"	Contains Alum
"WHITE LILY,"	Contains Alum
(Jewett & Sherman Co., Milwaukee, Wis.)	
"MONARCH,"	Contains Alum
(Ricker, Crombie & Co., Milwaukee, Wis.)	
"ONE SPOON,"	Contains Alum
(Taylor Manufacturing Co., St. Louis, Mo.)	
"IMPERIAL,"	Contains Alum
(Sprague, Warner & Griswold, Chicago.)	
"HONEST,"	Contains Alum
(Schoch & Wechsler, St. Paul, Minn.)	
"ECONOMICAL,"	Contains Alum
(Spencer Brothers & Co., Chicago, Ill.)	
"EXCELSIOR,"	Contains Alum
(L. E. Taylor, Chicago, Ill.)	
"CHARTRES,"	Contains Alum
(Tbomson & Taylor, Chicago.)	
"GRANT'S,"	Contains Alum
(J. C. Grant, Philadelphia.)	
"GIANT,"	Contains Alum
(W. F. McLaughlin, Chicago.)	
"QUEEN,"	Contains Alum
(Star Chemical Works, Chicago.)	
"PEERLESS,"	Contains Alum
(Marden's, Rochester, New York.)	
"ZIETLOW'S" SUPERLATIVE,	Contains Alum
(New York.)	
"RISING SUN,"	Contains Alum
(C. O. Strutz & Co., Chicago.)	
"SIBLEY, DUDLEY & CO.'S,"	Contains Alum
(Chicago.)	
"LAKESIDE,"	Contains Alum
(C. O. Perrine, Chicago.)	
"FRENCH,"	Contains Alum
(Thomson & Taylor, Chicago.)	
"DONNOLLY & CO.'S,"	Contains Alum
Premium Yeast Powder, (San Francisco.)	
"CHAMPAGNE,"	Contains Alum
(J. S. Taylor & Co., San Francisco.)	

Yours, very truly,  
HENRY A. MOTT, Jr., Ph. D., E. M.  
New York, Jan. 5, 1879.

Having obtained the foregoing, the reporter called at the office of the Royal Baking Powder Company, No. 171 Duane street, the manufacturers of the Royal Baking Powder, a brand which the report of the Brooklyn Health Board revealed to be pure. Mr. J. C. Hoagland, President of the Company, gave the following replies:

REPORTER—"What is the cause of the present excitement about baking powders?"

MR. HOAGLAND—"It is due to the substitution of alum for cream of tartar by some manufacturers."

REPORTER—"Have you ever used any alum in the Royal Baking Powder?"

MR. HOAGLAND—"No, sir."

REPORTER—"But I find that it is used by others. What is it used for?"

MR. HOAGLAND—"I presume because it is cheaper than cream of tartar, which it replaces."

REPORTER—"You would, therefore, obtain a larger profit by using alum than by using cream of tartar?"

MR. HOAGLAND—"Yes, for a time such substitution would more than double our profits."

REPORTER—"Why, then, do you not use it?"

MR. HOAGLAND—"For two reasons: first, the authorities on this point are so positive and conclusive that the continued use of alum in this way is dangerous to health, that we could not conscientiously use it; if others choose to take risks on the public health, we shall not follow them, preferring to continue the use of pure grape cream of tartar, which is demonstrated to be wholesome; second, our experience during twenty years has satisfied us that that which is best for the public is best for us. We can not afford to peril the reputation of the Royal Baking Powder."

REPORTER—"Can you give me any information in regard to cream of tartar, how and where you procure it?"

MR. HOAGLAND—"Certainly! There are several substitutes or patent 'cream of tartars' on the market, made principally from terra alba or burnt bones, the latter being treated with strong corrosive acids, but the cream of tartar we use is a fruit acid—it exists naturally in the Grape—and during fermentation of the tart wines in France, it is deposited on the sides and bottom of the casks. In its unrefined state it is called crude tartar or argols, and is taken from the cask after the wine has been drawn off. Each farmer has his crop of it according to the amount of wine he has produced. This company is the largest user of cream of tartar in the world, and we have our agents in various parts of Europe collecting the crude material. It is imported into this country as argols, and then subjected to a higher process of refining, by which it is purified especially for our purposes, forming

pure white crystals, which we grind to powder, and in this form we use it as an ingredient of our Baking Powder."

Other interviews were had, all to the same general effect, namely, that alum is used by many manufacturers to cheapen their powder, and enable them to undersell their competitors. Many of them are probably ignorant of the evil effects of alum on the system, while others are indifferent so long as they make money, and no one can be said to have dropped dead from taking their powder.

By this exposure of the injurious effects of alum in Baking Powder, the public must not be frightened from using baking powders when properly made. In the report of Professor Elwyn Waller, Assistant Health Inspector of New York Board of Health, on Baking Powder in 1872, the public are recommended to purchase one of the well-known brands of baking powder, in preference to purchasing the cream of tartar separately, as this substance was found in all cases to be adulterated. The inspector further states that when the mixture is made on a larger scale in a factory, and the baking powder is put up in packages ready for use, the manufacturer experiences no difficulty in securing good materials free from adulteration.

Dr. Mott, the Government chemist, in his review of the subject in the *Scientific American*, makes special mention of having analyzed the Royal Baking Powder, and found it composed of wholesome materials. He also advises the public to avoid purchasing baking powders as sold loose or in bulk, as he found by analyses of many samples that the worst adulterations are practised in this form. The label and trade-mark of a well known and responsible manufacturer, he adds, is the best protection the public can have.—HARPER'S WEEKLY.

## THORBURN'S SEEDS.

Our General Catalogue of  
**VEGETABLE,  
FLOWER,  
FIELD AND  
TREE SEEDS**

for 1880 will be ready for mailing early in the month.

J. M. THORBURN & CO.,  
15 John St., New York.

## Toes Protruding! Soiled Stockings!

**SHOE BILLS DOUBLE IN AMOUNT  
WHAT THEY NEED BE.**

All these ills prevented by purchasing for children's wear either the **A.S.T.C.**

**BEAUTIFUL BLACK or SILVER  
TIPPED SHOES.**

Everywhere known and prized for  
Skill and fidelity in manufacture,  
Tasteful and excellent improvements,  
Elegant variety of designs,  
Yielding unrivaled tones.

Brattleboro, Vt.

## Steam - Engines.

More effective and more complete, and more readily adapted to the various mechanical and agricultural uses than any other in the market. Practical improvements accumulated from twenty years' manufacturing experience, with reputation maintained and success established. Send for Circulars, descriptive and containing testimonials concerning our **PORTABLE and AGRICULTURAL STEAM ENGINES.**  
WOOD, TABER & MOISE, Eaton, Madison Co., N. Y.

**B. K. BLISS & SONS.**  
**HAND BOOK.**  
 A COMPLETE GUIDE FOR  
 THE GARDEN & FARM  
 SEEDS, PLANTS, BULBS, SMALL FRUITS  
 GARDEN REQUISITES. 300 ILLUSTRATIONS  
 150 PAGES. PRICE 10 CTS.  
 34 BARCLAY ST. NEW YORK.

### Bliss' Illustrated Amateur's Guide to the Flower and Kitchen Garden.

A descriptive list of 2,500 varieties of Flower and Vegetable Seeds, with explicit directions for culture, and much practical information upon the subject of Gardening. 220 Pages—Two Double-Page Chromos. 500 Illustrations.—Price 35 cents in paper covers. Bound in cloth, \$1.00.

Illustrated Catalogues of Plants and Small Fruits mailed free to all applicants.

### PRINGLE'S NEW Hybrid Spring Wheats, Champlain and Defiance, Two of the Best and Most Productive Varieties on Record.

1791 lbs. CHAMPLAIN, 528 lbs. DEFIANCE, GROWN FROM A SINGLE POUND OF SEED.

128 Bushels to the Acre. Heads from five to seven inches long, producing from seventy-five to one hundred kernels per head.

50 to 75 Strong Stalks from a Single Grain. Descriptive Illustrated Circular mailed free to all applicants. Price of each variety, per lb. 40 cents. 3 lbs. for \$1, by mail. By express, freight paid by purchaser, \$2 per peck; \$7 per bushel. 2 bushel bags of either variety, \$13.

### PEARL MILLET.

Clean Seed, 10 cents oz., 25 cts. ¼ lb., 60 cts. lb.; 4 lbs. \$2.25, by mail, post-paid, by express at expense of purchaser, 40 cts. per lb. Prices to the trade will be given on application.

### Prickly Comfrey Roots.

25 cts. ¼ lb., 75 cts. lb., by mail, post-paid, by express 50 cts. lb., 5 lbs. \$2. Directions for cultivation accompanying each lot.

### Dioscorea Batatas—Chinese Yam.

A valuable esculent, quite hardy, remaining in the ground over winter without protection. When cooked they possess a rice-like taste; are quite farinaceous, nutritive, and valuable for food. It is a very desirable climbing plant. Small tubers, in packets of one dozen, 20 cents; \$1.50 per 100; 1 year-old roots, \$1.25 per dozen; \$6.00 per 100.

B. K. BLISS & SONS, 34 Barclay St., N. Y. City. P. O. Box 4129.

### FOR 1880.

136 PAGES BEAUTIFULLY ILLUSTRATED. The best work on GARDENING. It contains descriptive price lists of VEGETABLE and FLOWER SEEDS and CHOICE PLANTS, with every thing for the garden. Copy, with large Chromo of New COLEUS, 10 cts.; plain copy, 6 cts. for postage. Wholesale list for Florists and Market Gardeners free.

HENRY A. DREER, Seedsmen and Florist, 714 Chestnut St., Philadelphia, Pa.

## SEEDS

OUR NEW 1880 EDITION contains Variegated Lima Bean, Mammoth Tours Pumpkin, New Excelsior Watermelon, Prize Paragon Tomato, Green Frolife Cucumber, Sutton's Siskin Peas, Yellow Spinnach and an improved New Radish. The whole 10 pkts., at retail, are worth \$1.00, but will be sent, post-paid, in a neat box, for only 25 cts. Burpee's Seeds are popular wherever grown, and this great special offer is made to introduce them to thousands of new customers. Burpee's Flower Seeds are finest in quality and lowest in price. Your choice of all varieties at 5 CTS. PER PKT., 25 PKTS. FOR \$1.00. Our popular collections of 10 PKTS. for 25 cts.; 20 Varieties for 50 cts. FOR ONE DOLLAR we will send, post-paid, 40 PKTS. of Garden, Field and Flower Seeds. Full directions for culture printed on each packet of the above. Postage Stamps taken. Order now. Burpee's Farm Annual for 1880, enlarged and fully illustrated, telling all about Seeds, Plants, Small Fruits, Blooded Livestock, Fancy Poultry, Dogs, &c., sent free to any address. W. Atlee Burpee & Co., 221 Church St., Philada., Pa.

### A NEW VARIETY!

Examined and Endorsed by Agricultural Department at Washington. A Large and Luscious

### HYBRID TOMATO.

Superior to all other Species, taste and flavor assimilating orchard fruit. This species of Tomato, the Yellow Large and Red Medium, each equally delicious in flavor, may be procured in packages of about 50 seeds, and will be sent to any address on receipt of 25 cents. Address: SEVERIN MILLER, P. O. Box 34, Davenport, Iowa.

## Farm & Vineyard for Sale.

Rare Chance for a Good Investment.

Address Lock Box 15, Geneva, N. Y.

Peach Trees for everybody. Applied to a wide range of climate. Small Fruits, etc. Price list free. R. S. JOHNSON, Stockley, Del.

## Three New Potatoes.

1. **Pride of America.**—In appearance resembles the Snowflake, a few days later; very productive, large size, an excellent keeper; of superior quality.

2. **Matchless.**—Tubers very handsome, round; pale red; flesh fine, rained, pure white, and of excellent quality. A great cropper, an excellent keeper.

3. **Silver Skin.**—A cross between the Early Rose and White Peach Blow. Tubers medium to large. Skin smooth, silvery white, russeted. Flesh snowy white, fine grain, splendid quality, an excellent keeper.

Prices of each of the above, \$1.00 per lb., 3 lbs. \$2.50, by mail, prepaid. By freight or express at purchaser's expense, ¼ Peck, \$3.00; 1 Peck, \$5.00; ¼ bushel, \$7.00; Bushel, \$12.00; Barrel, \$25.00.

**Alpha.**—The earliest variety known, and of extra fine quality—matures its crop in 55 days. 60 cts. per lb., 3 lbs., \$1.25, by mail. Peck, \$1.00, bushel, \$2.50; barrel, \$6.00.

Bliss' Illustrated Potato Catalogue, contains a descriptive list of all the new varieties recently introduced, with many other desirable sorts, beautifully illustrated. Centennial collection of 500 varieties. Also much useful information upon the cultivation of this valuable esculent. 10c.

## RELIABLE ONION SEEDS.

Our stock of Onion Seed has been raised from selected bulbs, and carefully tested, and we can recommend it with the greatest confidence, as equal to any ever offered in this or any other market.

In lots of 5 lbs. and over, 10 cents per lb. may be deducted. Postage must be added at the rate of 16 cents per pound when ordered by mail.

## Ask Your Merchant for

They are NOT sent out all over the country to be sold on commission.

They are NOT put up in Fancy Picture Papers, illustrating improbable vegetables.

They are NOT to be found for sale in grog shops.

They ARE grown by the subscribers on their own farms in Pennsylvania, Virginia, New Jersey, and Wisconsin.

They ARE put up in plain paper, at the lowest cost.

The purchaser, therefore, pays for seed and not for fancy paper and printing.

They ARE sold by respectable Merchants, Druggists, Grocers, etc., who buy them outright, because they know they will prove satisfactory to their customers.

They ARE to be had in any quantity in papers—in ¼ lb. packages, in pints of Peas, Beans, and Corn, or in Bulk.

If your Merchant does not keep them, send for Landreth's Rural Register and Almanac, containing catalogue and prices, and order them direct from headquarters.

DAVID LANDRETH & SONS,

21 and 23 South 6th St., Philadelphia, Pa.

## GRAPE VINES.

Also Trees, Small Fruits, &c. Wholesale rates very low. Nurserymen, Dealers, and Planters.

Send stamp for Descriptive List. Price List free.

J. T. LOVETT,

LITTLE SILVER, Monmouth Co., N. J.

## NEW SEED WAREHOUSE.

THE FIRST TO INTRODUCE EUROPEAN PRICES,

allowing purchasers to make their own selection of Flower and Vegetable Seeds in packets, at the extraordinary discount of 33% per cent. from Catalogue rates.

CATALOGUES SENT FREE TO ALL.

## DESIRABLE NOVELTIES.

**Early Washington Tomato.**—A very handsome variety, of perfect form, smooth as an egg, and rich, deep-red color. Fully a week earlier than "Acme," as solid as "Trophy," and decidedly superior in flavor. Per packet, 15 cts.

**Carrara Rock Cauliflower.**—The earliest variety known; produces beautiful, compact, snow-white heads of the finest quality. Resisting heat and drought, it will head where other varieties fail. Per packet, 50 cents; half oz., \$6.00; oz., \$10.00.

**Coral Flesh Musk-Melon.**—(From Japan.) A very early, densely netted variety, of round form and medium size. The rind is remarkably thin, while the suffused coral flesh is thick, deliciously crisp and melting. Per packet, 25 cents.

A. D. COWAN & CO.,

AMERICAN SEED WAREHOUSE,

114 Chambers Street, New York.

My Annual Catalogue of Vegetable and Flower Seed for 1880 will be ready by January, and sent free to all who apply. Customers of last season need not write for it. I offer one of the largest collections of vegetable seed ever sent out by any seed-house in America, a large portion of which were grown on my six seed farms.

Printed Directions for cultivation on every parcel. All seed sold from my establishment warranted to be both fresh and true to name; so far that should it prove otherwise, I will refill the order gratis. As the original introducer of the Hubbard and Marblehead Squashes, the Marblehead Cabbages, and a score of other new vegetables, I invite the patronage of all who are anxious to have their seed fresh, true, and of the very best strain. NEW VEGETABLES A SPECIALTY.

JAMES J. H. GREGORY, Marblehead, Mass.

## SEEDS

Western Seeds beats the world. Mine takes the lead. Fresh, pure cheap and warranted. Prices below every firm. I give more extra as presents than all firms. # THE MAPES COMPLETE MANURES FOR EACH CROP.

A few Reports (Extracts) from well known Potato-Growers and Farmers in the Use, during the past Season, of the **MAPES POTATO MANURE**.

Messrs. TEN EYCK BROS., Truck Growers, etc., Matawan, N. J., report Nov. 1, 1879: "Yield on eight acres nearly 1,600 bushels of potatoes. No acre fell below 180 bushels per acre, while some parts of the field did not fall short of 240 bushels per acre—95 per cent marketable. Land was in poor heart. The yield of the rows left unfertilized was too poor to be considered of any market value; the difference was so great as to make it difficult to state the degree. The season might be called a good average one, until the heavy rains that occurred in August, which seemed to have a killing effect on the vines of the earlier sorts. A marked difference of more than two weeks were unexpectedly seen in the early maturing effects of these fertilizers, over a good dressing of coarse yard manure, which was clearly proved on a separate piece, planted with the same variety of potatoes, and the yield one to four in favor of the special manures, and of far better quality. "Having had an experience of over thirty years in this line of business, we are firmly convinced that better paying results will follow the judicious use of your Concentrated Manures for farming crops, than in the use of the stable manures of the cities, at such prices as they seem to command."

"The cost of these potatoes, grown as above, for the manure, including freight, cartage, and spreading, was **twenty-three cents a barrel**, or about **eight cents a bushel**. If there be a purchasable manure that will reduce that cost under like circumstances, we should like to learn what it is, and where it can be had."

Messrs. E. & J. C. WILLIAMS, Nurserymen, Montclair, N. J., state in their last issued catalogue that they grew during the past season from a single barrel of their "Late Rose Potatoes," 210 bushels with the Mapes Potato Manure.

Mr. JOHN T. LOVETT, Vice-Pres., "American Association," writes, Jan., 1880: "I had startling results from the use of the Mapes Potato Manure the past season on poor light land. Had finer potatoes, and more of them, than my neighbors who paid four times as much money for stable manure."

Mr. FREDERICK MORTON, Rocky Hill, Conn., reports, Oct. 21st, 1879: "On very poor soil, natural yield only 25 bushels per acre, grew 200 bushels potatoes per acre with 400 lbs. of the Mapes Potato Manure. The potatoes grown with your manure were all of two weeks earlier than those grown with stable manure (10 cords applied per acre)."

Messrs. W. B. & O. C. KNAPP, farmers, Round Hill, Fairfield Co., Conn., report, Dec. 15, 1879: "Think the Mapes Potato Manure worth its cost in keeping the worms from eating the crop. 400 lbs. per acre, broadcasted and harrowed in, produced a much larger yield than grown with either barn-yard manure or compost of hen-manure, ashes, and plaster."

Mr. S. D. BURROWS, Basking Ridge, N. J., writes, Dec. 23d, 1879: "One handful, scattered in each hill at time of planting, yield was equal to a heavy coat of yard-manure with wood-ashes."

Mr. W. T. PARKER, Little Silver, N. J., writes, Oct. 24th, 1879: "The Mapes Potato Manure used at the rate of about 400 lbs. per acre, alongside of 25 tons of compost to the acre, costing \$30 without adding cost of handling. Saw but little difference in the crop. Used the same rate (money value) of the Mapes Manure as compared to the compost, and it nearly doubled the crop."

Mr. ANDREW N. DEBAUN, Oradell, Bergen Co., N. J., writes, Dec. 22d, 1879: "The Mapes Potato Manure has made a grand impression in this section. The potatoes generally looked poorly in all cases without the fertilizer. Barn-yard manure did not seem to tell in the early part of the season, and the dry weather we had was likely to affect those most that were late in maturing. Had 260 bushels per acre Early Rose Potatoes with the Mapes Manure. 126 bushels per acre on natural soil. My Clawson Wheat grown with the Mapes Complete Manure ("A" Brand) took the first premium at our County Fair."

Mr. A. P. WAKEMAN, Fairfield, Conn., writes, Dec. 16th, 1879: "Potatoes grown with the Mapes Potato Manure were large, smooth, with very fine flavor. They did not rot, while in the same field, side by side, where I used well rotted manure, at the rate of 15 two-horse loads per acre, with plaster in the hill, they rotted quite badly."

Mr. LEWIS BEACH, New Castle, New York, reports, Nov. 16th, 1879: "Soil gravelly and high; corn stubble; yield from natural soil, 140 bushels; with barn-yard manure, 180 bushels; with same quantity of barn-yard manure, and 400 lbs. of the Mapes Complete Manure, 284 bushels per acre. The potatoes grown with the Complete Manure were of superior quality and size. They received the First Premium at the Agricultural Fair at Yorktown. The Potato Manure prevented the grubs from depredating, and increased the crop fully fifty per cent above the yard-manure alone."

Mr. JOSEPH CORY, Westfield, N. J., reports Dec. 9th, 1879: "Yield of Early Rose greater from an application of 800 lbs. of the Mapes Potato Manure (costing \$30) than from thirty-nine loads of stable manure at two dollars per load—total, \$78. 400 lbs. of Mapes' Beet and Mangold Manure per acre broadcast yielded 1,020 bushels beets per acre. 40 loads stable manure yielded 840 bushels per acre, and the natural soil 437 bushels per acre."

## Some other Crops grown with the MAPES MANURES past Season.

**450 BARRELS CAULIFLOWER** from 1½ acres—and 225 bushels potatoes per acre.—JOHN CAMPBELL, Cutchogue, Suffolk Co., N. Y.

**500 BUSHELS ONIONS** per acre—350 bushels with stable manure, and 250 bushels per acre on natural soil.—F. W. PUGSLEY, Poughkeepsie, N. Y.

"**600 BUSHELS PER ACRE** of as nice onions as ever grew."—"One bushel of the White Onions took the **First Premium** at the Norwalk Fair. It would have been useless to have tried to get half a crop without the Mapes Onion Manure" (Complete Manure for light soils).—CHARLES A. MEERER, Southport, Conn.

"This is the first special manure I ever used that grew a crop of onions equal with hen manure."—A. N. HOUSE, Chester, N. Y.

**105 BUSHELS WHEAT** from 3½ acres; 200 bushels potatoes per acre on light soil; Turnips far superior in size and quality to those raised with barn-yard manure.—HENRY C. HERRING, Spring Valley, N. J.

**FIVE PREMIUM CROPS OF ASPARAGUS** grown during the past three seasons at Oyster Bay, exhibited at Spring Exhibitions in Mineola, L. I., were raised with the MAPES ASPARAGUS MANURE. Successful competitors were VALENTINE FROST, Locust Valley, L. I., and GEORGE H. TOWNSEND, Glenhead, L. I.

**44 BUSHELS BARLEY** per acre on heavy loam.—J. LAWRENCE SANFORD, Southampton, Suffolk Co., N. Y.

**PREMIUM POTATOES** "grown with the Mapes Manure—Queens Co. Agricultural Society, Town of Oyster Bay."—RICHARD C. COLYER, Woodbury, L. I.

**PREMIUM POTATOES**, "Best Early Rose," grown with the Mapes Manure—Agricultural Fair at Mineola, L. I.—T. CARLL BAYLIS, Mineola, L. I.

**PREMIUM ROSES**, Sweet Williams, etc., grown with the Mapes Manure—Queens Co. Agricultural Fair, Mineola, L. I.—WM. A. BURGESS (Dorris), Glencove, L. I.

**TWELVE Medals and Awards** given to the Mapes Manures by the State Agricultural Societies and Institutions in Connecticut, New Jersey, and New York States during the past two years.

These Manures are all **READY-MIXED**, in **FINE, DRY** condition, and **EASY OF APPLICATION**.—Full Directions for use and all information required for their use accompany **EVERY PACKAGE**. These Manures have been repeatedly subjected to Analytical Test by the leading Chemists and State Inspectors at the Stations—and **IN NO INSTANCE HAS THE STRENGTH OF ANY ONE OF THESE MANURES BEEN FOUND TO BE BELOW THE STANDARD**, fully given, in percentages, on each tag. Send for New Pamphlet (1880). Address

**THE MAPES FORMULA AND PERUVIAN GUANO CO., 158 Front Street, New York.**  
**BRANCH STORE AT HARTFORD, CONN.**

Experiment Set "A," \$7.00.—"Complete Manure" Experiment Set, \$5.00. Descriptive Pamphlet, "Farm Experiments," prepared by Prof. W. O. Atwater, and Blanks for Reporting Experiments, enclosed with each Set "A."

Strawberry Plants. Early  
Prolific, Reliance, Cuthbert,  
Queen of the Market, Throck (red), Florence (yellow), Gregg  
(black), 50c. a dozen. Sharpless. Miner's G. P. Glendale,  
Cinderella, Duchesse, Continental, Crescent, Monarch, Pioneer,  
Seth Boyden, Forest Rose, 30c. a dozen. Purity and genuineness  
of plants and safe arrival guaranteed. Send for a descriptive  
circular and list of lowest wholesale prices. Address  
**GIBSON & BENNETT, Woodbury, N. J.**

**1,000,000 SHARPLESS Strawberry**  
**Plants.** Noted for Great Vigor,  
Productiveness, Large Size, and Best Quality for Market  
and Family Use. Get Plants direct from Central Pennsylvania,  
"the home of the Sharpless," and be sure they are  
genuine. Descriptive Catalogue free.  
**J. L. DILLON, Florist, Bloomsburg, Pa.**

**STRAWBERRY PLANTS**—Pure, Well Grown,  
Packed free.  
Charles Downing, Crescent Seedling, Wilson Albany, Cap-  
tain Jack, Kentucky, and Monarch of the West, at \$1.30 per  
1,000. Boyden No. 30, Champion, Cumberland, Triumph, and  
Cinderella, at \$1.50 per 1,000. Miner's Prolific, \$3 per 1,000.  
Sharpless, \$8 per 1,000. For prices of 40 other sorts, or for  
large lots, see Catalogue or write for special rates. Please  
Address **J. S. COLLINS, Moorestown, N. J.**

**STRAWBERRY PLANTS.**  
All the new and standard kinds. Illustrated Catalogue  
sent Free. **C. S. PRATT, AGT., North Reading, Mass.**

**STRAWBERRY PLANTS.** Sharpless Seedling  
in large quantity. Raspberry and Blackberry Plants  
in variety. **Asparagus.** Prices from \$4 per 1,000. Send  
for Guide to Strawberry Culture and Price List.  
**WILLIAM H. MOON, Morrisville, Pa.**

**SHARPLESS,** 40 cts. per doz.; \$1.50 per 100, post-paid.  
Other kinds lower. **SNYDERS,** \$6 to \$10 per M. Lists  
free to all. **STONE LAKE NURSERY,**  
(Formerly Steele Bros.) La Porte, Ind.

**THE CRYSTAL CITY STRAWBERRY** is  
undoubtedly the earliest variety known. It proved it-  
self the earliest last spring, by being in the market several  
days before any other strawberry from any part of the State.  
Send for Circular and Price List to  
**E. WILLIAMS, Crystal City, Jefferson Co., Mo.**

**FAIRVIEW NURSERIES.** ESTABLISHED 1835.  
Sharpless, Miner's Prolific, Queen of the West, and 100  
other good kinds of Strawberries, all the choice Raspberries  
and other small fruits. Peach Trees, Osage Orange, and  
small fruits, specialties. All kinds fruit and ornamental  
trees, Shrubs, and Roses. Prices never lower. Price list  
free.  
**J. PERKINS, Moorestown, N. J.**

**Thousands of Cuthbert** Raspberry were planted  
this season before it was advertised. Plants and root-cuttings  
for sale. Catalogue free. Prices low. Rockland Co. Nur-  
series, **A. T. BLAUVELT & CO., Blauveltville, N. Y.**

**30 Acres Big Berries.** Currants, Grapes, etc. 100 best seeds. Plants  
by mail or express. See our prices before buy-  
ing of others. Illustrated Catalogue free.  
**G. H. & J. H. HALE, So. Glastonbury, Conn.**

## H.W. JOHNS' ASBESTOS Liquid Paints.

ARE STRICTLY FIRST-CLASS PURE  
LINSEED OIL PAINTS.

THE BEST IS THE CHEAPEST.

These are the purest, finest, richest and most durable  
paints ever made for structural purpose. They are prepared  
ready for the brush in sixteen newest shades and standard  
colors, suitable for the tasteful decoration of dwellings and  
all classes of buildings, inside and out, and for all purposes  
where a perfect protective coating is required, and, cover-  
ing body and durability considered, they are twenty-five per  
cent cheaper than the best White Lead or any other kind  
of paint now in use.

Our Asbestos Liquid White has been adopted for inter-  
ior and exterior work of the U. S. Capitol at Washing-  
ton.

The Metropolitan Elevated R. R., of New York City,  
is painted with our paints.

**ASBESTOS ROOF PAINT.**—Brown, Red, Yellow,  
Gray, Slate, and Cream, for tin and shingle roofs, iron work,  
agricultural implements, fences, outbuildings, etc. We  
guarantee this to be a better article than has ever before been  
offered to the public for similar purposes.

Samples of Colors and Descriptive Price-Lists by Mail.

**H. W. JOHNS' MFG CO., 87 Maiden Lane, N.Y.**

Manufacturers of Asbestos Roofing, Boiler Cover-  
ing, Steam Packing, Sheathing, Cements, Coat-  
ings, etc.

## THE DINGEE & CONARD CO'S BEAUTIFUL EVER-BLOOMING ROSES

**THE BEST IN THE WORLD.**  
Our Great Specialty is growing and distributing these  
Beautiful Roses. We deliver Strong Pot Plants,  
suitable for immediate bloom, safely by mail at all post-  
offices. 5 Splendid Varieties, your choice, all labeled,  
for \$1; 12 for \$2; 19 for \$3; 26 for \$4; 35 for \$5;  
75 for \$10; 100 for \$13. Send for our New Guide to  
Rose Culture (60 pp. elegantly illustrated) and choose  
from over Five Hundred Finest Sorts. Address  
**THE DINGEE & CONARD CO.,**  
Rose Growers, West Grove, Chester Co., Pa.

**ROSES**  
Catalogue free. **J. T. PHILLIPS, West Grove, Chester Co., Pa.**

**Roses and Greenhouse Plants. 12 Plants for \$1.00.**  
Lady Agents wanted in every town. Send for Catalogue.  
Address **WM. B. REED, Chambersburg, Pa.**

**OVER 1200 DISTINCT VARIETIES**  
**SPLENDID FLOWERS**  
All Strong Plants, each labeled, delivered safely by mail.  
Largest assortment. Low prices. In business for 26  
years. Guarantee satisfaction. Stock comprises all desirable  
varieties. Only mature plants sent. Our new Illustrated  
Hand-Book, sent free, contains the name and description of  
each plant, with instructions for successful cultivation. Do not  
purchase plants elsewhere before sending for our new  
Hand-Book. Every lover of flowers should have it. All  
buyers of cheap plants should have it. Every one wanting new  
and choice plants should send for our  
Hand-Book. **HOOPES, BROTHER & THOMAS,**  
CHERRY HILL NURSERIES, West Chester, Pa.

## ROSES AND GERANIUMS.

I guarantee safe arrival, satisfaction, stock equal to any  
in market.

100 by express for \$5. 50 by mail, \$3.  
Samples, 14 for \$1.10. Lists free.

**TYRA MONTGOMERY, Mattoon, Ill.**

## NEW HARDY PLANTS

In large and remarkable variety,  
including the  
**JAPANESE MAPLES.**  
Rhododendrons, Hardy and  
Greenhouse Azaleas, Camellias,  
Roses, Purple Beech, in large  
quantities.  
Also a complete assortment of  
Fruit and Ornamental Trees,  
Shrubs, and Vines.

Price Lists free. Descriptive Catalogues 10 cents.

**PARSONS & SONS CO. (Limited),**  
Kissena Nurseries, Flushing, N. Y.

**GEO. S. WALES, Rochester, N. Y.**  
**SMALL FRUIT PLANTS,**  
Seed Potatoes, etc. Circular free.

containing a great variety of Items, including many  
good Hints and Suggestions which we throw into smaller  
type and condensed form, for want of space elsewhere.

Continued from Page 90.

In justice to the majority of our sub-  
scribers, who have been readers for many  
years, articles and illustrations are sel-  
dom repeated, as those who desire in-  
formation on a particular subject can  
cheaply obtain one or more of the back  
numbers containing what is wanted.

Back numbers of the "American Agri-  
culturist," containing articles referred to  
in the "Basket" or elsewhere, can al-  
ways be supplied and sent post-paid for  
15 cts. each, or \$1.50 per volume.

**The German Edition.**—All the principal ar-  
ticles and engravings that appear in the *American Agriculturist*  
are reproduced in the German Edition. Besides  
these, there is a special department, edited by an eminent  
German cultivator. Our friends can do us a good service  
by calling the attention of their German neighbors and  
friends to the fact that they can have the paper in their  
own language, and those who employ Germans will  
find this Journal a most useful and acceptable present.

**Bound Copies** of volume 38, and of every pre-  
vious volume back to Vol. XVI. (1857), neatly bound, with  
gilt backs, Index, etc., are supplied at \$2 each (or \$2.30  
if to be sent by mail). See Publishers' Notes, 2d cover page.

**Clubs** can at any time be increased by remitting for  
each addition, the price paid by the original members;  
or a small club may be made a larger one at reduced rates,  
thus: One having sent 6 subscribers and \$7, may after-  
wards send 4 names more and \$3, making 10 subscribers  
for \$10.00; and so for the various other club rates.

**Terms to New South Wales, New Zea-  
land, Australia, Africa, etc.**—To several in-  
quirers. Under the latest revision of the Postal Union  
Regulations the price of the *American Agriculturist*  
(either English or German edition), including postage  
prepaid through, will be covered by 7 shillings sterling  
per annum. This applies to the above countries, and to  
all others embraced in the General Postal Union. The  
simplest mode of remittance is by Postal Money Orders,  
payable in London, to the order of Orange Judd Com-  
pany. These can be readily cashed in N. Y. City at a  
slight discount, which the publishers will cheerfully pay.  
For Club rates, (postage included), see our second cover  
page, and reckon 22 cents to the shilling sterling.

**Fish as Fertilizer.**—"J. C. D., Richmond, Va.  
The fish known as Menhaden, or Moss Bankers, are the  
kind used, merely because they are the most abundant;  
the oil is first pressed out of them, and the residue, dried  
and ground as Fish Guano, or Fish Scrap, is a regular  
article of trade with the dealers in fertilizers.

**Feeding Poultry.**—It is a common practice to  
throw the "chicken food" on the cold snow, sometimes  
where it is as deep as the fowls can well wade through,  
or even worse, into a regular mud hole. Neither of these  
methods is of advantage to the fowls; in the first case  
they are obliged to swallow a large amount of cold,  
chilling snow, and in the second, an amount of mud is  
taken into the stomach that is not desirable. All this  
discomfort could be avoided by providing a feeding  
trough, so arranged that the food may be clean. Aside  
from the looks of the practice, it will pay to be neat in  
feeding these animals that help to feed us.

**Honey Locust Seeds.**—L. Heading, and others  
will find at the end of an article on the Honey Locust,  
page 63, the information asked concerning the seeds.

**Artichokes—Jerusalem—Brazilian.**—Sev-  
eral inquiries. There is no such thing as Brazilian Arti-  
choke so far as coming from Brazil any more than there  
is one coming from Jerusalem. It is not at all likely that  
this native American plant was ever seen in either place.  
We have more than once explained how the name Jeru-  
salem came from a corruption of the Italian name *Girasole*.  
In France, where much more attention has been given to  
its culture than with us, they have nearly a dozen varie-  
ties. When some of our cultivators found that a short,  
round variety was more productive than the old fashioned  
long and slender one, they called it "Brazilian,"—a good  
enough name to distinguish that variety, but it should  
not be understood to indicate anything about its origin.

## Nuts and Nubbins.

A stuck-up thing—A show-bill.

Diet for prize-fighters—Pound cake.

A tornado is a great blow to any country.

We desire to be underrated only by assessors.

A musical instrument dealer advertises his drums that can't be beat."

Charles Lamb said of one of his critics, "The more I think of him, the less I think of him."

In a written-spelling exercise, "Foregoes" was given out: a little boy wrote, "Go, go, go, go."

When a cat gives an entertainment on the top of a wall, it isn't the cat we object to; it's the wail.

A man fell in a fit in a tailor's shop. His envious rival said, "That's the first fit ever seen over there."

Many a rough customer has never known how good he was until he killed somebody and heard the lawyer in charge sum up his virtues.

After a Texas jury had disagreed for ninety-six hours, the judge got a verdict in two minutes by sending in word that a circus was in town.

"How far is it to Butler, if I keep straight on!"—"Well, about twenty-five thousand miles, but if you turn the other way it's about half a mile!"

Editor: "Our friend W. has presented us with a basket of grapes, for which he will accept our compliments, some of which are two inches in diameter."

An old lady in Wichita says she never could imagine where all the Smiths came from until she saw in a New England town a sign, "Smith Manufacturing Company."

A washerwoman, commended by her pastor for regular attendance at church, said, "Oh, yes, after my hard week's work it rests me so to come and sit in church and have nothing to think about."

"Which do you think would be the easiest for me to change myself into—a lion, a horse, or an ass?" asked a conceited fellow of a friend.—"Oh, into an ass, as that would require the least change."

A c for an h. A cow jumped on the track before an express train. The report of the danger said: "As the safest way, the engineer put on full steam, dashed against the cow, and literally cut her into halves."

In answer to a Music Committee, an applicant wrote: "Gentlemen, I noticed your advertisement for an organist and music teacher, either lady or gentleman. Having been both for several years, I offer you my services."

"Mr. Smith," you said you once officiated in the pulpit.—"Yes, sir; I held the light to the man that preached."—"Ah! the court understood you differently. It supposed that you delivered the sermon."—"No, sir; I only threw light upon it."

A life insurance agent tells us that only last week a man insured his life for \$20,000, paying a single premium, and died the same night, and to-day his family has the money. He advises us to follow the good example. We'll think it over, and ask the family about it.

A Chicago man having put his new trotter to his best speed, proudly asked a policeman why he did not arrest him for fast driving, and was answered: "No cause, sir; you haven't driven fast enough yet to violate no ordinance."—A trotting horse was offered for sale in the next morning's papers.

Teacher (trying to explain repentance): "If a bad boy steals an orange, and his mother catching him at it, tells him kindly how wicked it is and how grieved she is, don't you think that boy ought to feel sorry?"—Scholar: "Yessum."—Teacher: "And why?"—Scholar: "Cause he hain't et the orange before his mother cotched him and took it away from him."

If men were turned out of office *only* when they behaved badly, or because others could perform their duties better, we should find their *chief attention devoted to the performance of good work*, because that would be the root of their tenure of office. Now their most earnest thought is how to carry the next election for their party, as therein lies their tenure of office.

A weary peasant taking his first railway ride on a pitch dark night, wished to take a nap, but was bothered to find a place for his huge three-cornered hat in the crowded car. "Here, put it in the cupboard, my good man," said a commercial traveler, opening the window. The drowsy peasant complied, murmuring his thanks, and expressing his ignorance of the ways and conveniences of the rail. He was soon in a sweet sleep; before he awoke the commercial traveler prudently found a seat in another car.

A rich and ingenious mechanic constructed a safe which he declared to be burglar-proof. To convince the incredulous of the fact he placed a \$500 note in his pocket, had himself locked in the safe, with a liberal supply of provisions, and the key cast into the river, declaring that he would give the money to the man who unfasted the door. All the blacksmiths and carpenters in the country have been boring and blasting at that safe for a week with every kind of tool and explosive mixture known to science, and the man is there yet! He has convinced everybody that it is the safest safe ever invented. Fears are entertained that the whole concern will have to be melted down in the blast furnace before he is released, and efforts are to be made to pass in through the keyhole a fire-proof jacket, to protect the inventor while the iron is melting.

A dilapidated old man entered a lawyer's office with a book under his arm, and looking around, apparently stupidly, inquired if he could see the lawyer. He was pointed to a sign reading: "Very busy just now; will see you later." The man went out. The lawyer heard that his visitor had a \$50,000 case. Much vexed, the lawyer tore down his sign. Soon after the man called again with a book under his arm, and was received with great cordiality. He sat down and asked, "Very busy this morning; I don't want to annoy you?"—"Oh, no, plenty of time now; you can't annoy me at all; I shall listen to you with pleasure."—The old man slowly undid the book and began: "I'd like to call your attention to this Life of Napoleon; it is said the engravings alone cost \$50,000, and yet the book is selling at only—"

**The Death of Alfred Gray.**—Just as we go to press, we see the announcement that Alfred Gray, Sec. of the Kansas State Board of Agriculture, died at Topeka, January 23d. No particulars are given of an event that will bring sadness to a wide circle of friends. We must at present content ourselves by saying, that no State has done more for her agriculture, than Kansas, and this has been largely due to the fact, that Alfred Gray was the most efficient Secretary. A practical farmer himself, he appreciated the needs of farmers, and worked most faithfully to supply them. Among the many pleasant recollections that cluster around the Centennial, are those of the delightful hours passed in the society of this most genial gentleman, and surely no State was more worthily represented, than Kansas in his person. The loss which Kansas sustains is a loss to the whole country.

**A Good Knife** is a good thing, and the further one is "off soundings," whether at sea, or beyond cities and stores, the more does he need a knife upon which he can rely. The cutlery sold in small places, and frontier towns, is much like the celebrated razors of Pindar, "made to sell." One who can be reached by mail, can be sure to get a good knife, a fact, duly set forth in its proper place.

**Young Forest Trees.**—The raising of most forest trees from the seed is not difficult, provided they can have the proper care in weeding, shading, etc. But this care is what the farmer who most needs the trees, is the least able to give, as it is demanded just at the time when he is busiest. We announced last year, that a great help was afforded to farmers in this matter by Messrs. Robert Douglas & Sons, of Waukegan, Ill. This firm which annually raises many acres of tree seedlings, last year tried the experiment of sending packages of young trees by mail. This was attended by such favorable results, that they propose to continue to do so this year. So greatly were we impressed with its importance, that in making up our list of useful articles for premiums, "Forest Trees by Mail," No. 129, were included. By supplying the farmer on the prairies with trees, that are, so to speak, beyond the dangers incident to childhood, tree planting is rendered a very simple matter, and it should lead to increased activity in this respect. The Messrs. Douglas say, and we doubt not, truly, that there is no appreciable direct profit in the enterprise, and that they hope to find their ultimate returns, in an increased love for tree-planting throughout the whole of the present treeless regions.

**Mixed Farming.**—Until our country is settled up, and the virgin fertility of the new soil is beginning to be exhausted, we can not hope for that safe and solid foundation for our agriculture which comes from Mixed Farming. When every farmer comes to that point when he knows that his land is a medium through which crude fertilizing elements pass in becoming food—vegetables, fruits, grains, flesh—he will feel the importance of a variety of products—a rotation of crops—and the value of animals in the economy of the farm. As our country grows older from necessity, if for no other reason, farmers will be more thorough students of their profession.

**Alkali Soils.**—"Red River," Grand Forks, Dakota, writes, there are patches of a few acres, in a place where the soil is so filled with alkali that nothing will grow on them, and asks why it is only in patches, and if anything can be done to get rid of it. . . . These alkaline patches appear when the subsoil is so impervious as to prevent all natural drainage. The water does not drain off after the rains, but is evaporated; water is continually brought to the surface from the subsoil by capillary attraction, and the salts it contains (Lime, Soda, and Potash), are left on the surface. The trouble can be remedied by draining, or by draining and irrigation. Drainage will give the water a chance to pass off, and in time the rains will wash out the excess of alkali. If irrigation can be employed, this washing out process will be much hastened. Irrigation without drainage would be of no use, for when the surface became dry again, the old state of things is restored. In some portions of Colorado, the reclaimed alkali soils are regarded as their most valuable land.

**Tree Peddlers Again.**—"J. M. L.," Vienna, Kans., writes that three persons came to his town pretending to be agents of a certain nursery in Illinois. They offered "Russian apples at \$1 each, claiming them to be imported from Russia at one year old, and to be borer proof, pear trees grown one year in France, and far superior to anything ever offered in this country, cherry trees grown one year in England, and peaches grown one year in Canada, and far superior to native trees."—We never heard of the nursery that these parties claim to represent, still there may be such. "They also claim that there are but four nurseries that import fruit in this way two of them in New York, one in Ohio, and this one in Illinois." Our correspondent asks: "Are there such apples as Russian Borer-proof, and are fruit trees imported in the manner stated, or is the whole thing a swindle, and is there any way to get out of receiving the

stock ordered?"—We get every spring and fall more or less letters of the same purport, from persons, who, persuaded by the representations of "nursery agents," give them orders, and afterwards suspecting that the stories are not true, repent of their haste, and write to ask if they are obliged to abide by their agreement. Of course if one has ordered trees under false representations, he can not be bound by his agreement. The trouble will be to prove that the representations are false. If the truth is known, it will probably turn out that every one who ordered trees from these chaps has signed a note which is held against him. They got the name by asking for his address, or in some other way. The chance of repudiating the order will depend upon what kind of a judge or justice "dispenses with the law" in the locality. Take the case in point: Russian apples are not "borer-proof," and they are only to be preferred to other apples in localities where their probable greater hardiness will allow them to endure the climate. Kansas does not need them. Pear, cherry, and peach trees of one year old, are not generally imported from the countries named, still it can not be *proved* that the trees were not imported. If it was claimed that the trees were any better for being grown a year in another country, that is a false representation. We have little doubt that the whole affair is a swindle. The trouble will be to convince the court of that should the case be brought up. All anxiety and trouble may be saved, as well as the future disappointment when the trees come into bearing, by the exercise of a proper caution. Every one should know that growing a peach in Canada, or a cherry tree in England, will in no manner alter its nature, and the mere fact that an apple was raised from the seed in Russia can not possibly protect its trunk from a Yankee borer. Still another way of avoiding trouble with tree peddlers, is not to buy of them at all, but purchase of well-known nurserymen.

## Sorghum in America—Its Introduction.

### An Interesting Bit of History.

In the spring of 1856, the Editor of the *American Agriculturist* received a small parcel of Sorghum seed from Messrs. Vilmorin, Andreux & Co., the noted seedsmen of Paris, who had brought it from China. It was planted in rich garden soil, and grew 13 to 15 feet high, maturing its seed well. The children of the neighborhood found the juices of the stalks so sweet that they used up a large part of the three rows 25 feet in length. A sketch of one of the plants was made and published, with a description, in this journal for February, 1857. It was subsequently announced that the seed would be distributed among our readers, to be divided equally among all who should send an envelope directed to themselves—say from 25 to 50 seeds each. This publication brought samples to the office from three other parties within 30 miles of N. Y. City. Soon after a stranger came in and tried hard to buy all our seed. When his offer reached \$8.00 a pound, he was informed that it would not be sold at any price, as it was already *promised* to our readers. He then produced a newspaper item from the West, where he had been traveling, and said the interest was so great that he could divide a pound into a hundred or more parcels and sell them quickly at \$1.00 a parcel. As soon as he left the office, the Editor sent out and bought all the seed in the three localities he had heard of, at \$5 a pound. At the same time he wrote to the Paris seedsmen to send him all the seed they had, and draw on him for the pay. To his surprise—consternation almost—they returned word by the next steamer that they had shipped 1,000 lbs. (no Atlantic Cable then) and held 600 lbs. more to his order. The whole was ordered at once, and when the 1,000 lbs. arrived it was immediately announced that none of it would be sold, but that a packet of at least 400 seeds would be *presented* to any reader of the *American Agriculturist* who desired it—enough to experiment with and to provide an abundant supply of plants the next year if it proved valuable. *Thirty-One Thousand* (31,000) Parcels were distributed to our readers throughout the country, and planted. Enough was saved and sent to Georgia to grow 34,500 lbs. (17½ tons) of seed, during the summer of 1857. This was sent to this office, and a full pound given to every reader desiring it for 1858—over 30,000 pound parcels were thus distributed.

From the above seed thus widely and freely scattered was produced at least nine-tenths of all the Sorghum grown in this country. (A small quantity was sent out from the Patent Office, and some sold by dealers). Hundreds of millions of gallons of syrup were made and used during the war when the usual supply of Southern grown sugar was cut off. It was worth many millions of dollars to the country. But such difficulty was experienced in producing good *sugar* that the cultivation fell off after the supply of South grown sugar came in. Quite a "boom" was started later on by high claims asserted for a variety called the African "Imphee," but this soon died out. Recently, the improved processes of obtaining the saccharine matter in crystalline form, as sugar, have given a new impetus, and very promising results are anticipated, as noted on pages 101-102.

## Catalogues Received.

When a catalogue includes more than one department of business—as Nursery and Greenhouse, we, as heretofore, place it under what appears to be the leading branch.

## SEEDSMEN.

HUGO BEYER, New London, Iowa.—Besides Vegetable and Flower Seeds offers Greenhouse Plants, Bulbs, etc.

J. BOLGIANO & SON, No. 28 South Calvert Street, Baltimore, Md.—One of the oldest houses in the country, and has several novelties, including the Queen Tomato.

ALFRED BRIDGEMAN, No. 876 Broadway, New York.—A year older than the above; a very compact, and ably illustrated list of everything in the trade.

JOHN LEWIS CHILD, Queens, Queens Co., N. Y.—Flower Seeds in half dime packets. Bulbs and Greenhouse Plants. Illustrated.

COLE & BROTHERS, Pella, Iowa.—Vegetable, Flower, and Farm Seeds; full, compact and illustrated.

CROSSMAN BROS., 300 Munroe Avenue, Rochester, N. Y.—A wholesale list of Vegetable and Field Seeds.

J. A. FOOTE, Terre Haute, Ind.—Vegetable and Farm and Flower Seeds. Neat, compact, and business like.

JAMES J. H. GREGORY, Marblehead, Mass.—Characteristic in every feature, especially in the many novelties and specialties. Also the Hubbard Squash.

E. M. HAVEN, Bloomington, Van Buren Co., Mich.—Vegetable Seeds and Hot-bed and Garden Vegetable Plants.

THOMAS MEEHAN, Germantown, Pa.—Special list of Tree, Shrub, and Fruit-tree Seeds.

T. M. METCALF, St. Paul, Minn., offer largely the growth of their "North Star Seed Farms." Also Small Fruits and Forest Tree Seedlings.

E. A. REEVES, No. 69 Cortlandt Street, New York, sends a neat illustrated list of Vegetable and Farm Seeds, and another for Flower Seeds, both very full and complete.

I. J. SIMONSON, No. 63 Barclay Street.—Send out separate catalogues for Vegetable and Flower Seeds, the selection in both very large.

WM. W. STERLING, Cutchogue, N. Y.—A select list of Vegetable Seeds of his own growing.

JAMES M. THORBURN & Co., No. 15 John Street, N. Y.—For nearly 80 years Thorburn's seed store has been known to New Yorkers; the catalogue is a wonder of capaciousness and compactness, and presents an innovation by being illustrated.

## NURSERYMEN.

GARRET H. BANTA, Riverdale, Bergen Co., N. J.—A select list of Fruit and Ornamental Stock, Evergreens, etc.

CHEERY & NEUSON, Nashville, Tenn.—Besides Fruits, of which there are many Southern varieties, very full in Evergreen and other Ornamental Trees and Shrubs.

JOHN S. COLLINS, Moorestown, N. J., sends his wholesale list of Small Fruits, etc.

ROBT. DOUGLASS & SONS, Wankegan, Ill.—To their usual wholesale list of Evergreen and Ornamental Tree seedlings add much interesting descriptive matter. Also a list of Forest Trees by mail.

ELLWANGER & BARRY, Rochester, N. Y., send a special list of Strawberries, with useful directions for culture.

THE GOULD NURSERY, Beaver Dam, Wis.—Selections with special reference to the climate of the Northwest in Fruits and Ornamental Stock.

CHARLES A. GREEN, Clinton, Munroe Co., N. Y.—Small Fruits, accompanied by a treatise on their culture.

DAVID HILL, Dundee, Ill.—Wholesale list of Evergreen and Forest Tree Seedlings, also older stock and Fruit Trees, etc.

KING & MURRAY, Flushing, N. Y.—This, the Bloodgood Nursery, shows no signs of age in its catalogue, except the statement that it was established in 1790.

J. T. LOVETT, Little Silver, Monmouth Co., N. J.—A full catalogue of Small Fruits with various specialties.

T. V. MUNSON, Denison, Texas.—Fruit and Ornamental Stock, with special reference to the wants of the State.

JOHN C. NELSON, Turner Junction, Ill.—Two very neat, compact, and comprehensive lists, one of general Nursery Stock, and the other devoted to Strawberries, with descriptions.

C. M. SILVA & SON, Newcastle, Cal.—Fruit and Ornamental Trees suited to the Pacific coast.

W. C. STEELE, Laporte, Ind.—A price list of Small Fruits in great variety.

H. M. THOMPSON & SON, St. Francis, Wis.—Seedlings of Evergreen and Deciduous Trees, Fruits and Tree and Shrub Seeds. Wholesale list.

B. F. TRANSOU & Co., Humboldt, Tenn.—A general stock of varieties best suited to the State, some of which are local.

F. TROWBRIDGE, Milford, Conn.—A Cranberry circular.

E. B. UNDERHILL, Poughkeepsie, N. Y., sends a neat and well classified list of Small Fruits, or "berry plants."

JOHN VAN LOON, New Amsterdam, Wis.—Small Fruits and others, with special reference to hardiness. Seeds and Ornamental Plants.

GEO. S. WALES, Rochester, N. Y.—Small Fruits, specialties in Vegetable Seeds and Vegetable Plants, also a treatise on Strawberry culture.

ZIMMERMAN BROS., Cameron, Mo.—A collection of Fruit and Ornamental Stock suited to the climate.

## FLORISTS.

THOMAS ELVERSON, New Brighton, Beaver Co., Pa.—Very full and excellent list of greenhouse and other Plants.

# STEEL BARB FENCE,

Solves the FENCE Problem by meeting all the requisites of  
**THE PERFECT FARM FENCE.**

**Every Land Owner** should not fail to examine the merits of this fence. It is cheaper than all others. Easiest handled, and in fact just what the people of the treeless States have needed for years.

**To All Inquirers.** It is an impassable barrier, yet harmless. Prohibits trespassing. It can be put up by any one, and is compactly put up for transportation. It fact, it is the only fence dog and wolf proof.

**Cheaper** than Wooden Fences. **Imperishable** when once in place. **Indestructible** by the Elements. **Waste no soil by SHADE.** Has no **Weedy Fence Borders.** **Shelters no Enemies of the Crops.** A **Protection** at all seasons. It is **easy of Construction.** It needs no repairs. Accumulates no snow-drifts.

## A STEEL THORN HEDGE.

**Impassable Barrier.** Prohibits all Trespassing. It can not be destroyed by fire, wind, or flood.

**100,000 miles of Barb Fence** have been erected in 1876, 1877, 1878. **Agriculturists, Herdsmen, Sheep Husbandmen, Ranchmen, Vineyard Proprietors, Orchardists, Nurserymen, Railroad Companies, Road Proprietors, and all owners and occupants of soil and areas to be protected.**

**Manufactured by Washburn & Moen Manufacturing Co.,**  
**WORCESTER, MASS., and 21 CLIFF ST., NEW YORK.**

# Powell's Iron Fence Posts

For Barb Wire, Iron, or Gas Pipe Fencing.

**Cheap, Strong, and Durable. No Digging Required.**

DIRECTIONS FOR SETTING POSTS.

First drive post with wrought iron guide in place, then drive cross-pieces through guide, which renders it more immovable than any other post, in the setting of which the ground must be displaced.

We make **Line Posts, also End and Corner Posts, either painted or galvanized, and Wire Strainers of an Improved Pattern.**

**ABRAM G. POWELL & CO.,**  
**829 Willow St., Philadelphia, Pa.**

PAT'D APRIL 1st, 1879.

## FRENTRESS STEEL BARBED FENCE WIRE

(Patented Dec. 14, 1875—Reissued May 22, 1877.)

**The Best and most Durable of all the Barbed Wires in Use.**

A sure protection, cheaper than board or rail fence, and good for a life-time. Has no weedy fence row. When the best costs no more than an inferior article, always look for the best. We claim for the **Frentress a Superiority over all other Wires.** For Circulars and Price Lists address

**FRENTRESS BARBED WIRE FENCE CO., East Dubuque, Illinois.**

## THE LATEST IMPROVEMENT IN BARB FENCE.

The cut shows exact size of strand and distance apart of barbs. Not dangerous to horses or stock. Price the same by the pound or rod. **SAMPLES SENT FREE TO ANY ADDRESS.**  
**AMERICAN BARB FENCE CO., 60 Clark St., Chicago, Ills.**

## Big Giant Corn Mill, Every Man His Own Miller.

The only Mill that will grind Corn with Shuck on without extra expense. The only Mill grinding Corn and Cob successfully, that will grind Shelled Corn fine enough for family use.

Grinds twice as fast as any other Mill of same size and price.

**CAN BE RUN BY ANY POWER.**

Capacity from 6 to 30 bushels per hour, according to size. Send for Catalogue and prices.

**U. S. WIND ENGINE & PUMP CO.,**  
**Batavia, Kane Co., Ill.**

## RUSSELL & CO.'S

## PORTABLE FARM ENGINE,

WITH THEIR

**"NEW MASSILLON" THRESHER,**  
Makes the Best THRESHING outfit known.

Ohio, Pennsylvania, and Wisconsin Testify.

From John Bechel, New Washington, Ohio.

Threshermen, look here. If you want a good machine this season buy the "New Massillon." It beats them all. No more growing about not threshing clean, or beater wrapping, or stirring at the riddles. That is all done away with. Start up in the morning and thresh till noon without stopping for anything.

I threshed 500 bushels of wheat and never stopped till all was out; could have threshed 200 bushels more before we had dinner.

Threshed 1,700 bushels of grain in one day; had to stake three times, and had to move two miles at that. The new riddle that is put in now clears ready for market.

I threshed 55 bushels of timothy seed in two hours, and 135 bushels in one-half day. How is that for high. I can beat anything that travels the highway in threshing any kind of grain; don't care where they come from; don't expect any of them.

Put the "Massillon" Engine and the "New Massillon" Separator together, and there isn't another machine made to beat it. Gentlemen, I am satisfied that I have the best machine in the United States. Have threshed twelve years and ought to know a little about threshing.

From Samuel Deppen, Herndon, Pa.

I had my threshing done this season by the "New Massillon" Separator and 10-Horse Traction Engine, and they gave me the best of satisfaction. It was the best work I ever had done. It threshes fast, takes all the grain out of the straw and chaff, separates and cleans it well, and don't cut or break it.

There is no choking or clogging of the machine.

From T. H. Austin, Janesville, Wis.

The No. 8 "New Massillon" Separator and 10-Horse Engine that I bought of your agent at this point, has given me the best of satisfaction, and after a full season's work I can say, without any hesitation, that it is a No. 1 outfit in every respect for fast and good work in all kinds of grain, and especially in timothy and flax. (A want long felt by every farmer, is now supplied by your "New Massillon.") I paid the cash for my outfit, after giving it the most severe tests, and being warned by agents and general agents of other so-called first class Machines and Engines that they were worthless.

But I bought your machine on my own judgment, paying very much more than I could have bought other machines for, and will say here that I can beat any or all who oppose you or your "New Massillon," for I can assure you that you have a world beater.

Address for Catalogue, Price Lists, and address of nearest agent,

**RUSSELL & CO., Massillon, O.**

## Agricultural

**Insurance Company, of Watertown, N. Y.**

Capital \$200,000.00. Net Surplus, \$216,645.62. Total assets for the security of Policy-holders, January 1st, 1879, \$1,150,063.99. Insures only Farm Property and Residences against fire and lightning. Takes no business risks.

## MILL MANUFACTORY

ESTABLISHED 1851.

**Grist Mills of French Buhr Stone.**

Portable Mills for Farmers, Saw Mills, etc. **18 Sizes and Styles.** Cost **\$2,000** in use **\$30** and upwards. Complete Mill and Sheller **\$95.** A boy can grind and keep in order. Adapted to any kind of suitable power. Complete Flouring and Corn Mill. **ALL SIZES.** Send for Circular No. 28. **NORDYKE & MARMON CO., Indianapolis, Ind.**

## CHICAGO SCREW PULVERIZER.

## Does Pulverization pay?

ABILENE, KANSAS, Nov. 10, 1879.  
I seeded 3,400 acres of wheat with these machines....The stand of wheat is now the best I have ever seen on new land.

R. J. WEYMESSE, Trustee.

DANVILLE, ILL., Dec. 4, 1876.  
This year I harvested, on 190 acres, 6,100 bushels of wheat. ....In my opinion the Screw Pulverizer increased the crop one-third over what I could have got by any other method.

D. G. MOORE.

Send for pamphlet with cuts, and over sixty letters from men who have the machine.

Chicago Scraper & Ditcher Co.,  
34 METROPOLITAN BLOCK, CHICAGO, ILL.

## NOTICE

To Every Farmer and Agent.

If you want a first-class, reliable, two-horse

**GRAIN DRILL OR CORN PLANTER,**

# \$1000. REWARD

For any Washing Machine that will Wash Cleaner, Quicker, with Less Labor and Wear and Tear of Clothes than the **ROBBINS FAMILY WASHER AND BLEACHER,**

THE ONLY PERFECT SELF-OPERATING WASHER IN THE WORLD.

No rubbing required. No more yellow clothes nor hard work on washing day. No more rubbing clothes full of holes. No more lame backs for farmers' wives washing harvest shirts. Seeing is believing, and if you will try it once, you will never again wash without it, nor use any other washing machine.

IT IS THE BEST IN THE WORLD, and will wash anything from a lace curtain to a horse blanket, and cannot get out of order.

Good Agents Wanted, both Male and Female, to whom Liberal Inducements are Offered.

AGENTS CAN MAKE FROM \$10 TO \$100 PER WEEK.

INDISPUTABLE EVIDENCE.

## "A Splendid Washing Machine."

This is what they call the Robbins Family Washer at the home of the business manager of "Farm and Fireside." Heretofore it required one woman a whole day from early morn till late at night, to finish the washing, and an extra girl to cook. But since we got a Robbins Washer one girl attends to the washing, cooks dinner at the same time, and has all the clothing hung out to dry, and tubs, wringer, and everything put away before 12 o'clock noon. We wish we could tell our subscribers how delighted they are at our house with this simple washer, and also get them to understand that we write this simply and entirely for their benefit, and not at the solicitation of the manufacturers, nor with their knowledge or consent; but we write this to let our readers know that the Robbins Washer has actually proven to be an article that does all the manufacturers claim for it, and really does away with a great part of the drudgery required in washing clothes. We would pay many times the price asked rather than do without one. We have also noticed that it requires less soap than formerly, so that the saving in the soap will in short time pay for the machine.—Springfield, O., Farm and Fireside, Oct. 1.

Publisher of Farmers' Review, Chicago, Ill., received a sample, and after giving it a trial, sends for \$24 worth for his friends and neighbors.

The publishers of the New York Christian Advocate, after receiving sample washer, say: "It requires to be honestly tried a few times only to convince the housekeeper that she has found a friend and economizer of labor in the Washer. We have confidence in commending it to the attention of our lady readers."

The N. Y. Witness says: "Several of our staff have the machines in use, and are well satisfied with them."

N. Y. Weekly Sun says: "The Robbins Washer and Bleacher is as represented."

The Toledo Blade says: "We believe it to be one of the greatest inventions of the age."

The Chicago Inter-Ocean says: "The company could not well say less of that truly wonderful article, which is destined at no distant day to work a complete revolution in the method of accomplishing the family washing. We speak from our own knowledge, as well as from the testimony of thousands who have already availed themselves of its services."

E. B. Mack, N. Y. office of the Cincinnati Gazette says: "I have one in use in my house and it does admirable work."

D. F. Raymond, Cincinnati, O., says: "Can I have Cincinnati and Hamilton County, New York and Covington, Ky., by ordering \$100 of Washers at once? Have waited to see what Washer would do; am delighted; does all you claim."

Again, December 9: "Inclosed please find draft for \$100 on Met. National Bank. Please hurry along the Washers."

C. H. Mather, Burlington, N. Y.,—After purchasing sample and "convincing the sceptical ones," orders \$24, \$75, \$30, \$24, \$65, \$24 worth in rapid succession.

W. P. Pratt, Frankfort, Mo.,—"I want the agency for your Washer and Bleacher. We have had one in our family for three years, and we think it an indispensable article. Several of our neighbors, I think, will buy."

J. H. Hill, of Camp, La., Jan. 23, 1880, writes: "My wife would not take fifty dollars for ours."

WE COULD FILL THE COLUMNS OF THIS PAPER WITH SUCH EVIDENCE. WILL PEOPLE BUY A HUMB-BUG THE SECOND TIME?

See October number of *Agriculturist*, page 374, article on "Washing Machines and Washers."

The above is no boastful offer, made only for the sake of selling our Washer, but, on the contrary, we mean exactly what we say, and will really give \$1,000 for any washing machine that can be proven better than ours before a competent committee. Any reader who doubts our ability to do all we agree, can easily be convinced by referring to the Mercantile National Bank of this city, to any express company in New York, or to the publishers of this paper.

SAMPLES PREPAID TO YOUR NEAREST RAILWAY EXPRESS OFFICE in any part of the United States east of the Mississippi and Missouri rivers, also Kansas and Nebraska, for \$3.50. West of that line as follows: Tu Dakota, at Bismarck, or Yankton, for \$3.50; in Wyoming, at Cheyenne, for \$3.50; in Idaho, at Franklino City, for \$4.50; in Colorado, at Denver, or Pueblo, for \$4; in New Mexico, at Santa Fe, for \$5; in Arizona, at Prescott, for \$8.50; in Utah, at Ogden, for \$4; in Nevada, at Virginia City, for \$5; in Louisiana, at New Orleans, for \$3.50; in Arkansas, at Little Rock, for \$3.50; in Texas, at Corsicana, for \$4.50; at Texarkana, Denison, or Sherman, for \$3.50. For the Pacific coast we will deliver No. 1 at San Francisco, Sacramento, Marysville, or San Jose, for \$4. Our reason for so doing is to induce people to investigate this matter, feeling assured that a trial will secure an agent for us.

Send for a sample and secure A BUSINESS THAT WILL PAY YOU WELL. No article in the world has so much MONEY IN IT FOR AGENTS as this Washer.

When you order or write, mention this paper.

Address

**Bissell Manufacturing Co.**

50 BARCLAY STREET, N. Y.

**CAUTION.**—We hereby warn all persons against making, selling, or using any washer working on the principle of the ROBBINS FAMILY WASHER AND BLEACHER. Many imitations are now being offered for sale, even going so far as to use the descriptive portions of our circular and advertisements in order to mislead the public. We will prosecute all infringements to the full extent of the law.

States of Minnesota and Wisconsin, on receipt of one dollar.  
Prices by keg on application.

**THE ADVANTAGE**  
of the Steel Center Self-Sharpening Shoe is that the calks  
are always sharp. A thin plate of steel is rolled inside  
of the soft iron bar from which the shoe is made. The soft  
iron in the calk partially wears away, leaving the sharp  
steel center, as shown in the cut. Address  
**SIOENBERGER & CO., Pittsburgh, Pa.** Agents for the  
United States except the States of Minnesota and Wisconsin.

The Bryden Concaved Steel Calk  
Horse Shoe. The most complete shoe  
made, with welded steel toe calk, and  
iron heel calks, hammered, not rolled,  
and equal in wear to hand-made work.  
This Shoe is easily fitted, hot or cold,  
has a perfectly level foot bearing, is  
light and durable, with a low crease  
to protect the nails from working  
loose. The cheapest and best Shoe  
for Horse Railroads, Carriage  
and Farm Horses, now made. Made in  
sizes 1 to 5, hind and forward. Send  
for circulars. **THE BRYDEN HORSE  
SHOE CO., 52 Broadway, N. Y.**

**"THE JOHN D. BILLINGS"**  
Patent Steel and Iron Horse-Shoe.  
Made complete, with Level Spring Plat-  
form—Continuous Calk. The best for  
Horse-Railroads, Farm, and Carriage  
Horses in the world. Cures Tender and  
Contracted Feet, Corus, Interfering, Quar-  
ter-crack Lameness, and all evils  
resulting from the use of the com-  
mon shoe. Trial Set, with Nails,  
\$1.00. To measure, place foot on  
paper, and draw pencil around.  
Shoes put on cold. No heating of  
foot. Send for free Illustrated  
Pamphlet. **THE JOHN D. BIL-  
LINGS PATENT HORSE-SHOE**

# Maynard's Rifles and Shot-Guns.

**Our New Off-Hand Rifle.**

For hunting and target practice, at all ranges, the "MAYNARD" more completely supplies the wants of hunters and sportsmen generally, than any other rifle in the world, as many barrels can be used on one stock; and for ACCURACY, CONVENIENCE, DURABILITY, and SAFETY, is not excelled. The following are some of the scores recently made at Walnut Hill, by members of the Massachusetts Rifle Association: J. N. Frye, President, in All-Corners' Match, 15 shots, 200 yards, without cleaning, 54555555-34; L. L. Hubbard, Executive Officer, 200 yards, off-hand, 45555555-49; O. M. Jewell, 300 yards, off-hand, 5455555-34; O. M. Jewell, 300 yards, off-hand, 5555555-35. For illustrated price list, address

## POTATO BUG. COTTON WORM. CANKER WORM.

**THE BEST INSECTICIDE EVER USED.**

## London Purple.

(Trade Mark.)

Sold by all Wholesale Druggists and Stores throughout the United States. It is not obtainable of nearest dealer, send direct to sole manufacturers, **HEMINGWAY'S LONDON PURPLE COMPANY (Limited), 60 Mark Lane, London, England.**

A. R. WHITNEY, Franklin Grove Orchard and Nurseries, Lee Co., Ill., writes: "We have had the Canker Worm a long forewell, and have done it with your LONDON PURPLE. We put in about three-fourths to one pound of LONDON PURPLE to 44 gallons of water, and applied with a force pump. It is better than Paris Green, as the particles of LONDON PURPLE adhere to the leaves and Paris Green does not."

## AGENTS WANTED to Sell the NEW BOOK, FARMING FOR PROFIT

## THE NEW BLANCHARD CHURN THE NEW

We have perfected a radical and valuable improvement in our celebrated Churn, which needs but to be seen to be appreciated. Now offered for the first time to the dairy public.

It received the HIGHEST PREMIUM at the International Dairy Fair in New York City, in competition with all the leading churns in the market.

Nine sizes made, churning from one to one hundred gallons. Warranted to be exactly as represented.

Send to any dealer in REALLY first-class Farm and Dairy Implements for a Descriptive Circular of "THE NEW BLANCHARD CHURN," or to the Sole Manufacturers, **PORTER BLANCHARD'S SONS, Concord, N. H.**

## Cooley Creamer

Awarded Gold Medal at Paris Agricultural Exhibition, 1879.

Butter made by this process awarded Sweepstakes at International Dairy, at New York, 1878. Two Gold Medals and First Premium on Dairy Butter at same Fair, 1879.

It requires no milk room. It raises all of cream before milking. It affords best ventilation to milk. It is more thoroughly made.

It is cheaper. It requires less labor, and gives better satisfaction than any other way of setting milk. Send for "Dairyman," giving full particulars and testimonials.

**VT. FARM MACHINE CO., Bellows Falls, Vt.**

## DAIRY SUPPLY CO.

261 and 263 Greenwich St., New York.

Offers complete outfits for large and small BUTTER DAIRIES, of the newest and of the best apparatus and appliances.

The most approved and simplest apparatus for securing, cooling, and delivering pure milk and cream a specialty. Ice Chests, Refrigerators, and Cold-Rooms, estimated on and contracted to order.

Class Bottles and Jars for individual milk delivery. Butter Packages for square or round prints with molds to match.

Airtight Butter Packages for holding two to ten pounds in crates of 45 to 60 lbs.

Milk-Setting Appliances.—Cooler pails, do. ventilated, with and without windows to inspect depth of cream. Creamers, "Bureau" and "Cabinet" Creameries in variety, etc.

## The Perfect Milk Pail. The Pendulum Churn.

Our specialties, and the best of their kind in the world. Address as above.

## REID'S Creamery.

The simplest, best, and most convenient yet invented.

**AGENTS WANTED.** Send for circular to

**A. H. REID, 6 N. Eighteenth St., Philadelphia, Pa.**

## AMERICAN VEGETABLE FIBRE CO.

## FLAX & HEMP RESTORED TO AMERICA!

Great impediment removed from Flax and Hemp in the United States, by the Maching of the American Vegetable Fibre Co. Each of the Awards above named was accompanied by the warmest approval of the Judges examining the invention. The speed of its action, and the completeness of its work, surprises all witnesses. The dependence on coarse hand labor, which destroyed our trade for nearly 50 years, is now removed by the substitution of this most ingenious Machine, which will fill the dreary gap between the cultivation and manufacture of these and similar Fibres, and thus restore to us the long lost "Golden Fleece." Illustrated Pamphlets, giving full particulars, sent by mail on application to **American Vegetable Fibre Co.**

**JOS. F. DUNTUN, Manager,**  
213 South Front St., Phila., Pa.

Secured by letters patent.

**THESE PUMPS HAVE RECEIVED THE  
"MEDAL OF SUPERIORITY,"**  
The highest award of the American Institute  
for 1878 over all competitors.

These pumps have enormous power, and are for the house  
or for out-door wells of any depth. They are constructed  
with special regard to strength,  
ease of working, and durability.  
They can be immediately  
changed from lift to force pumps,  
and the air chamber can be re-  
moved, so as to allow the handle  
to work at any desired angle with  
the spout. Having close tops,  
they cannot be tampered with.  
Attention is called to our new  
elegant pattern **DEEP WELL  
non-freezing FIRE PUMP.** Also, Blunt's Sand Vacu-  
um Chambers.—A complete  
protection against sand or gritty  
water in dug or driven wells,  
pits, mines, and rivers.  
For hand or steam pumps,  
all sizes, from 1½-inch to 4-inch  
standard pipe.

# CHAMPION REAPERS & MOWERS.

## VICTORS OF THE EXHIBITION.

The **CHAMPION** was awarded 2 Grand Medals at the International Exposition, Chili, South America, in 1875. Five of the Highest Honors at Centennial Exhibition at Philadelphia in 1876. Two Gold Medals and a Work of Art at Universal Exposition in 1878 at Paris, France, and the Highest Prizes at National, State, District, and County Fairs, innumerable.

Among its lesser triumphs in 1879 was the Prize awarded by the Queens County (N. Y.) Agricultural Society. The competitive trial was held at Mineola, L. I., in June, 1879, and, as there has been considerable feeling manifested at the results, we append an autographic report of the Draft Record, as furnished by the Secretary of the Society:

J. Howard Rushmore,  
Secretary.

## MONARCHS OF THE FIELD.

The **CHAMPION** is the Acknowledged Superior of All Grain and Grass Cutting Machinery,

And Fully Endorsed by the Best Expert Authority, after the Most Thorough Tests, as to its Capacity and Execution,

AS THE

Most Wonderful Machine Ever Invented.

**REMEMBER**, under no circumstances should you buy a Reaper or Mower until you have examined **THE CHAMPION**. Whenever you hear of one of these **Machines** in your vicinity, do not fail to examine it thoroughly. Its **Lightness of Draft**, its Marvellous Movement, its Simplicity, and its Automatic Adjustment to every condition of the field, can not fail to commend it over all others. Farmers will be more than ever satisfied, when they investigate its manifold claims of superiority and test its numerous advantages, that the **CHAMPION** is certainly the Machine to be preferred.

It is estimated by the most competent Judges that over one half of the Hay and Grain Crop in the United States is harvested with **Champion Mowers and Reapers**.

Information in every particular furnished on application.

**An Elegant Imported Cornet,  
WITH SUPERB CASE,**

**ONLY  
\$15.00**

**A BARGAIN NEVER EQUALLED.**

These Cornets were designed and manufactured in Paris expressly for us, and have all the late Parisian improvements. The workmanship on them is par excellence, as no expense was spared in their construction. The design and finish is simply elegant, while their **sounding powers and brilliant tone is marvellous**, equal to any \$25.00 Cornet ever offered. Each instrument has all the crooks and set-pieces for Bb, A, Ab, G & F, and is packed in an elegantly trimmed compartment case, with lock and handle. Each purchaser sending cash with orders we give free of all cost our **Complete Teacher** for the Cornet. REMEMBER these figures are **WAY UNDER PRICE**, as we MUST REALIZE AT ONCE. Sent C. O. D., with privilege of examination before buying, on receipt of \$3.00 as a deposit. CHARLES W. STORY, 26 Central St., Boston, Mass.

[TRADE MARK.]

## Veterinary Cosmoline

Is a heavy oleaginous hydro carbon of the consistency of an ointment, derived exclusively from petroleum. It is absolutely free from acids, alkalis, or moisture. When applied to wounded and inflamed flesh, it is a perfect protection against atmospheric action, flies, insects, animalcules, preventing the generation of microscopic organisms, and allowing nature absolute freedom to heal itself rapidly by a healthy granulation without sears. Never has there been a veterinary ointment that would heal so rapidly all the wounds, sores, and surface diseases of horses, cows, sheep, poultry, etc. For sale by Druggists. **Price 75c. in lb. cans.** Descriptive circulars mailed in answer to postal cards. E. F. HOUGHTON & CO., 211 South Front Street, Philadelphia, Pa.

## THE NEW BOSS HORSE HOE.

For General Purpose Work it is **Strong, Practical, and Cheap**; it **Cultivates, Hoes, and Weeds** out the rows. Sold only from manufactory. Address WM. PERRY & SON, Canandaigua, N. Y.

**A Single Bag Sold at Ton Rate. No Cartage Charged.**

**The Mapes Potato Manure.** Price per ton, \$18. Per Bag (200 lbs.), \$4.80. Use three bags per acre—in drills or hills.

**840 Bushels Potatoes (Burbanks), from 10 bushels seed on two acres.**

WILLIAM S. ROBINSON, MATTITUCK, SUFFOLK CO., L. I., FEB. 28th, 1880, reports:—

"Soil, good loam; season good for potatoes; planted last of April Burbank seedling potatoes; applied four bags per acre (costing \$20), of the Mapes Potato Manure; Fertilizer was applied in the drill.

Planted 10 bushels of seeds on certainly not two acres of land, and got 840 bushels of good potatoes; not over two bushels in one hundred of small ones.

Used 800 lbs. of the MAPES POTATO MANURE per acre and nothing else; probably the heaviest crop ever raised in Suffolk County."

**The Mapes Grass and Grain Spring Top-Dressing.**

Price per Ton, \$51. Per Bag (200 lbs.), \$5.10. Spread broadcast on Grass or Grain—two bags per acre in spring—earlier the better.

**Wheat and Permanent Grass—The Mapes Wheat Manure Compared with Stable Manure.—Years 1877-'78-'79.**

VALENTINE FROST, LOCUST VALLEY, L. I., FEB., 1880, reports:—

"In fall 1877, seeded down with wheat and applied broadcast, 1,000 lbs. per acre of the MAPES WHEAT MANURE. The land was excellent wheat and grass land when well manured. The yield of wheat was heavy and of fine quality; in 1879 the first mowing of grass cut heavy; crop was "down" two weeks before cutting. Where I used stable manure the yield was not, in any case, any better than from the Mapes Manure and the cost was more than double. The season was tolerably favorable.

I had two lots; one of eight acres and one of six acres; on the six acre lot I put 300 loads of New York Stable Manure on half of it (3 acres); and on the eight acre lot put 400 loads of New York Stable Manure on four acres, a half of it. On the remaining portions, half of each lot, I put 1,000 lbs. of the MAPES WHEAT MANURE per acre. Both yielded excellently of wheat. The grass was extraordinary fine, the advantage being if anything in favor of the Mapes Manure through all the years. The point is, that the Mapes Manure costing \$25 per acre, was fully equal if not better than the New York Manure, the latter costing \$55 to \$60 per acre, independent of great saving in cost of application."

"Have used the Mapes Manures four years with good results, and use them in increased quantities each year."

**The Mapes Complete Manure (for light soils).** Price per Ton, \$51. Per Bag, \$5.10.

This is our Manure for Onions, Cabbages, and all Garden truck on all soils, and for Grass and Grain Crops, seeding down, on light soils.

**The Mapes Corn Manure.** Price per Ton, \$49. Per Bag, \$4.90. For practical results in the use of all these Manures during past season by farmers, truckers and others, see *American Agriculturist* March No., page 114. These Manures are all ready mixed, in fine, dry condition, easy of application. Full Directions for use and Analyses accompanying every package.

Send for new pamphlet (1880). Pamphlets mailed gratis. Address

VOLUME XXXIX.—No. 4.

NEW YORK, APRIL, 1880.

NEW SERIES—No. 399.

CLEARING UP A FARM.—DRAWN BY R. E. ROBINSON.—Engraved for the American Agriculturist.

The history of the first century of the settlement of this country is one of forest-felling and land-clearing. The labors, trials, and hardships of those who in early days engaged in a struggle with the wilderness can only be appreciated by those who have made or are now making for themselves and their families a home in the wild, wooded regions still unoccupied. To go into the woods and "clear up" a farm is no easy task; and the scene which is presented in the engraving will carry the thoughts of many of our middle aged readers back to the days of the hardest work of their lives, but days that were bright in the hopes of future comfort and prosperity. Before the corn and wheat could grow, or the green pasture furnish food for the stock in summer, and the meadow its burden of hay for the winter, the trees must be felled, the tangled brush be burned, the virgin soil broken, and the seed sown in the rough, but rich and willing ground. All this

demanding toil, and toil of the most severe kind. But what changes were wrought! Every tree brought down opened a new space on the ground below, and a new inlet for the sunlight above; every stump or every stroke of the axe was an encouragement for the next. Look now at the aggregate results of this labor. A wild, savage country transformed into a peaceful, prosperous land of plenty. In some cases the change was slow, and several years elapsed before the land was thoroughly subdued to cultivation; but often the transformation has been so sudden as to almost make one doubt his senses. In the space of a few short months the unbroken forest, known only to the Indian in pursuit of his game, was changed into open fields of waving grain. The wonderful story of the changes that accompanied the progress of the settlement of our forest regions, seems like fiction to him who has always lived in a long settled or prairie country.

But to one who returns after a few years absence from the forest-side home of his boyhood days, the change is real. The woods have been swept away as by a whirlwind, and the picture that he has long held so dear in his memory, no longer exists in reality. The land has been "cleared up" and even the stumps of the old trees have yielded to slow decay or the more rapid blasting dynamite, and the mower and reaper run smoothly over the ground. Year by year the "wood lots" have been narrowed in, until they are now in many cases too small to furnish the proper protection from stormy winds to the wide open stretches of country, or against other sudden, violent meteorological changes. The desire to get all the acres into grain and grass has been too strong, and the results are not to the country's advantage. We may from necessity be called upon to restore by the slow process of plant-growth what has been destroyed as by fire.

**Bee Plants.**—"J. F. Z." Isanti Co., Minn. But little has been done in this country in the way of growing plants expressly to furnish pasturage to bees. One of the strongest claims that bee-keeping has upon farmers is, that it utilizes that which would otherwise go to waste. To devote land and the labor of raising plants to the bees would put the business upon a very different footing, whether it would be profitable or not remains to be tested. In a conversation with the late Mr. Quinby on this subject, he stated that the plant which seemed to him the most promising for cultivation was the common Catnip. This is a perennial, and a field once stocked would remain for several years; it blooms in summer when other honey-flowers are scarce, and it is said that the product is very white and of great delicacy of flavor.

## Calendar for April, 1880.

## AMERICAN AGRICULTURIST.

NEW YORK, APRIL, 1880.

## Hints for the Work of the Month.

[The Hints and Suggestions in these columns are never copied from previous years, but are freshly prepared for every month, from the latest experience and observations, by practical men in each department.]

**Spring work** comes without hurry to the farmer who is prepared. Much of the mischief laid to unfavorable seasons rightly belongs to a laggard beginning. A well started crop rarely fails to be satisfactory in spite of weather, and a late one is rarely so.

**Early Planting and Sowing.**—With the soil well prepared, early sowing is most desirable with many crops. Some tender ones make a poor start unless the ground is warmed by the sun and air, and a late frost may do harm. But it is rarely wise to delay because of what may happen, when promptness promises the best results.

**The Condition of the Soil** is always to be taken into account. Fields that are drained, either naturally or artificially, may be safely sown when a wet soil cannot be. Wet soils are cold. Some deny this, on the ground that the water is as warm as the soil, and has no refrigerating effect. But it is the circulation of air in the soil that warms it, and if it is so filled with water that air cannot enter, it remains cold, until the water has evaporated.

**The First Crop to be Sown**, is spring wheat, then oats; after these come beets and potatoes. Wherever spring wheat will succeed it is a desirable crop, even when sown in April. Out of its natural district, which is marked out by peculiarity of climate more than any other condition, it is of no use to sow it, unless in a small way to experiment with new varieties of unusual promise.

**Barley.**—A fine condition of the soil is indispensable for this crop. Old barley growers know all about this, but many want to grow barley because it is a profitable crop when successful. It will succeed in any good, well prepared soil, but a mellow clay loam which can be brought to good tilth is to be preferred. But good crops of bright grain may be grown on lighter loams if in good heart. It may be made an excellent soiling crop to follow clover, and as a change from oats. We prefer to sow thickly, say 2½ bushels per acre, but opinions vary in this respect, and from 1½ to 2½ bushels is the range.

**Oats.**—Early sown oats in our hot climate are, as

a rule, better than the late sown. Our climate is not so favorable for oats as the cooler northern and northeastern ones. There oats are heavy and plump, and seed from Canada, Nova Scotia, and New Brunswick will produce well for two or three years. By using seed from these northern localities, oats may be grown in the Middle States weighing from 35 to 45 lbs. per bushel.

**Flax.**—It is supposed that flax is a "hard" crop on land. It is true in one sense, but it will not injure a cool, moist soil that has a fair proportion of vegetable matter in it. It has been grown with oats and threshed for feeding, and there are few more profitable crops than this mixed one. A large demand is springing up for both seed and fibre. Mills are becoming numerous. But it should not be lost sight of that mills will not come until there is some material to be worked up, and if the farmers of any locality wish for a factory near them, they must first grow the needed material. It is fortunate that flax can be grown for feed, and even the straw used for fodder when mixed with oats, so that a good foundation may be laid for a supply for flax mills. The same is true of

**Sugar Beets.**—After many years of trial and failures, the manufacture of beet sugar promises to become successful. It depends wholly on the farmers. To retain in our midst the millions of dollars sent abroad for sugar, is desirable. The Portland, Me., Sugar Factory Company, after several seasons of work, still perseveres in inducing the Maine farmers to produce roots, and is sanguine of success. Beets can be grown profitably if a determined attempt is made. Let but one acre, or less, be planted and well tended, and as soon as that can be grown successfully, 10 acres may be.

**Plant Early.**—Beets need to be put in very early. The seed should go in the ground immediately after the last harrowing, and if the seed be soaked to ensure quick germination, the young plants will get a start of the weeds. The writer's practice has been to do this with all kinds of roots, and as soon as the green line of the plants can be seen, to run down the rows with a hand cultivator that cuts on both sides of each row, and stirs the ground within an inch of the small seedlings. By keeping the plants cultivated in this way the middles may be left without harm for some time, as the rows are kept distinct, and can be readily seen when the horse hoe is used.

**Plant by Hand.**—Steeped seed cannot well be sown by a machine; by steeping, the quality of the seed is discovered. A light furrow may be made and the seed dropped in it so closely as to consume 6 or 8 lbs. of seed per acre. The rows may be covered by the hoe or by a roller run over the ground across the rows.

**Fertilizers.**—No other crop requires a more vigorous start than roots. A liberal application, at planting, of artificial fertilizer, Peruvian guano or special root manure being preferable, will go a great way to ensure success. It is well to scatter the root manure along the rows as they are opened, drop the seed and then cover. This prevents too close contact of seed and fertilizer which is often dangerous. Guano needs to be more thoroughly mixed with the soil.

**Corn.**—This is one of those crops which require a warm soil and which suffer from a late frost. But the ground may be prepared in season to help on the planting afterwards. As good a crop may be grown on stubble as on sod if the right method is followed; and this is simply to give sufficient manure and thorough cultivation. 100 bushels per acre may be produced, and this means double or treble pay for the same labor. Far larger crops than this have been grown, and of late years, thanks to the general diffusion of scientific knowledge through the best of the agricultural journals, the average yield of this grain has been doubled. A yield of 75 or 80 bushels is now secured where 30 or 40 bushels used to satisfy farmers. The use of fertilizers and good methods of cultivation have effected this; but the same means may be made available for even larger yields, and one should never stay satisfied with a large crop, but try for

still greater ones. The time of planting of course varies with the latitude, and these remarks apply when corn-planting is in season.

**Grass.**—With a doubled yield of corn and productive crops of roots, more land can be laid down to grass. The cheapest and the most essential product of the soil is grass. The better the system of agriculture the better will be the grass produced. Orchard grass for dry soils, and Red-top for low land are now thought more of than heretofore. A study of the character and value of the best grasses and their cultivation and protection is now of great importance. "Flint's Grasses and Forage Crops" is a useful book for this purpose.

**Seeding to Clover.**—Clover seed sown this month will do well in many localities, if scattered upon ground previously harrowed with a smoothing harrow, which passes over the grain without injury, and fertilized with a light top-dressing of fertilizer.

**Soiling Crops.**—The first cutting of green fodder is winter rye, that which is first cut will make a second growth that can be cut in June. An early sowing of oats, oats and peas, or oats and barley, should be made this month for cutting after clover. Soiling crops are sown in succession weekly, so as to have succulent fodder continuously.

**Peaches.**—As the old favorites, the Peach Blow, Mercer, and others, gradually failed and run out, so our newer favorite, Early Rose, seems doomed, as a field crop. Unfortunately we cannot as yet lay our hands upon a perfect substitute. Some promising new varieties are offered which are worthy of trial. One of them is mentioned on page 148. As a rule seed procured from a northern locality yields better than home grown seed.

**Live Stock.**—The coat is now changed and good brushing or carding helps the shedding of the hair by stimulating the skin.

**Medicines** are to be avoided as a rule, excepting in extreme cases. "Spring physic" is an old notion which should rest with our ancestors. If due attention has been given to feeding and general care, stock will come out in good order after their season of dry feeding and confinement.

**Horses.**—When hard work commences, dry food will be needed. It hardens the muscles and prevents excessive perspiration. The skin, tender from long rest, is easily chafed and galled. Cold water and Veterinary Cosmoline will keep galls in check and heal raw spots. Clean, soft harness, prevents galls. Shoes that have been long on ought to be removed, and in paring the hoof let no knife touch the frog. It will wear away fast enough.

**Cows.**—Garget and abortion trouble the dairymen. We believe in prevention. The former may surely be prevented by due care. As soon as the udder contains milk, it should be relieved by drawing off a part of it, if there is any tendency to hardness. These diseases are often a consequence of weakness. A fat animal may be weak for want of food. When a cow's time approaches and the feed is suddenly reduced, disturbance of the system is caused. Circulation becomes irregular, and congestion occurs in the most susceptible organs. The udder is the principal one of these at this period, and an attack of garget is very sure to occur. This may not always be so, but long experience and observation convinces us that it generally is. The remedy is obvious.

**Sheep and Lambs.**—As lambs grow and thrive, ewes suffer. All the growth of the lamb comes from the ewe. The suggestion should carry its own moral, viz., feed the ewe. There is no food so nourishing for a lamb as the dam's milk, and plenty of it produces the finest lambs. Cow's milk may do for a store lamb, but not for a market lamb. Ticks will become troublesome and fret the flock. The use of a strong decoction of Tobacco will destroy these pests.

**Swine.**—Corn is high, but so is freight, and as 800 lbs. of corn may be carried in a pork barrel, it is a question if it will not pay to feed 50 cent corn to 4 cent pigs. Every bushel of corn fed relieves the market of a surplus, and makes the remainder more salable. This is to be considered. Also the fact that there is a kind of pig that may be fed the most

profitably and that one kind is the one to discover and choose. Hereafter farmers will save their profits in all probability, just as is done in other manufacturing business. Animals are living farm machines.

**Poultry.**—Vermin run riot among the poultry and many poor fowls die of diseases caused by the constant worryment of lice and fleas. As the weather grows warm this is to be looked after, and the flock freed from the pests. Free use of kerosene oil or crude petroleum, about the roosts and crevices of the nests, and clean earth in the runs and houses will effect a deliverance.

**Machinery.**—After the winter's rest an overhauling of the machines will be proper. Dust and rust should be cleaned off, and oil and tallow used liberally. It should be understood that there is more wear from rust than from use, with farm machinery.

## Notes on Orchard and Garden Work.

### Orchard and Nursery.

Whoever sets out an orchard of course does it with the expectation of a return in fruit. No one plants corn or potatoes without first considering if the land will give him a crop; if the soil is not in the proper condition he knows that he must make it so, or lose his seed and his labor. Much less than corn and potatoes can fruit trees make a crop on nothing. The trees will struggle along, do the best they can, but such orchards do not pay, and "run out" early. Unless the land is sufficiently fertile for an ordinary farm crop, it should be made so; no soil too wet for such crops will answer for fruit trees, which, to succeed, need well drained land. The plowing should be as deep as the character of the soil will allow, and the sub-soil plow may generally follow the other with benefit.

**The Trees.**—It is assumed that trees were ordered some time ago; they should be at hand ready for planting. It is the custom at nurseries to take up and heel-in a large stock of the kinds of trees most called for, this retards the growth, and allows them to fill late orders. If there is a nursery near at hand it will pay to make a bargain, if possible, to help dig the trees yourself, and thus secure a larger share of the roots that belong to them. If trees, in a long journey, become dry and shriveled, bury them, root and branch, in mellow earth for a few days, when they become plump again. In unpacking the trees, look to the labels, as some may become detached and would otherwise be lost.

**Laying Out.**—In staking out the ground take care to have the trees in true rows. Put all of the same variety together, and if there are many kinds make a planting chart showing the position of each.

**Preparing the Trees.**—Everybody wishes to get all he can for the money, and the nurserymen send much larger tops to the trees than the pruned roots in their new positions can support. It is safe to shorten the branches one-third or one-half, but it should be done with judgment and reference to the condition of the roots. At the same time pare smooth any broken or mangled roots.

**Planting.**—In setting a tree take time to do it properly; spread the roots evenly and to their full length, and so work in the soil among them that there will be no hollow places. Water may be used to carry the soil among the roots—not dashed in by the pailful, but showered from a watering-pot. Do not stamp the soil down around the roots, but firm it carefully with the foot. The tree should be set no deeper than it stood in the nursery.

**Crops.**—The soil of a young orchard may be kept in cultivation until the trees begin to bear; grain should never be grown, except Indian corn, but potatoes and root-crops are the best.

**Grafting.**—A tree that is of a poor or worthless sort should be renovated by grafting. This can be done this month; for full particulars with illustrations of the process see the February number.

**Cions** should have been cut early, but may be secured until the buds start. Many nurserymen cut a stock of cions of all the leading varieties in advance, and can supply them by mail or otherwise.

**Root-Grafts.**—Those who would start an orchard at a very small outlay, can begin with root-grafts.

These are roots in which grafts are set; the work is done in the winter and the grafted roots kept in boxes of earth until they can be set out in spring. Many nurserymen offer these for sale, and they are the cheapest form in which trees can be bought. They are to be set 2 feet apart, in rows distant enough to work with a cultivator, and put in with a dibble so deep that only the top bud is above ground. Keep them well cultivated, and 90 per cent, or more, should be thrifty young trees in autumn. In 2 or 4 years, according to the variety, they will be large enough to set in the orchard.

**Insects.**—Destroy the eggs of the Tent Caterpillar, which are to be found in small closely fitting rings or bands near the ends of the smaller twigs, and may be cut away. Many insects harbor beneath the loose bark of trees, and by scraping this off and washing the trunk and limbs with a solution of soft soap, much good may be done. To prevent the ascent of the wingless females of the Canker Worm, use heavy brown paper bound closely around the tree's trunk, and then smear with cheap printer's ink or tar. The bands will have to be re-coated at frequent intervals through the season.

### Fruit Garden.

Those having the planting of small fruits still to do, will find hints in last month's Notes.

**Currants and Gooseberries.**—Prune at once any that have been omitted; abundant manuring and mulching will increase the size of the crop and the fruit. So soon as the leaves are of much size the "worms" may be expected. Examine the under surface of the lower leaves for the eggs, and destroy all that are found. When holes are seen in the leaves apply White Hellebore, either sprinkled dry or mixed in water, a tablespoonful or so to a pailful of water. It is better to first scald the Hellebore with a little boiling water before adding it to the pail containing the cold water. Keep stirred.

**Strawberries** receive treatment on page 149.

**Grapes.**—Vines can still be planted and should be set out by all who have a spare corner on the place, as along a fence, or by the side of a shed. Under ordinary care a few vines will give an abundance of nice fruit in its season, and every farmer should feel that he has a place for a few grape vines. See the article on page 149.

### Kitchen and Market Garden.

**Cold Frames.**—The plants from these are to be set out so soon as the soil is ready, and the sashes used on other frames to push forward a crop of lettuce, which latter, when out of the way, is to be followed by cucumbers—thus making the most out of the investment in glass. At this season the frames should have an abundance of fresh air, and while generally open during the day, they must be shut at night and in cold days.

**Window Boxes** may be placed out of doors on warm days to harden off plants; they may be left out overnight when not cold enough to chill them.

**Sowing Seeds.**—The plants of the vegetable garden are divided into two general classes, *hardy* and *tender*. For a list of each and their treatment, see last month's Notes.

A **Marker** can be easily made from a piece of scantling for the head piece into which the handles and pegs are fastened. The pegs may be 9 inches apart on one side and 12 on the other. A line is used as a guide in making the first rows, after which, by allowing the outside peg to run in an old mark, all the rows may be straight.

**Greens** were so fully treated last month, page 104, that it need only be referred to here.

**Asparagus.**—The old ideas about the elaborate preparation for an asparagus bed are out of date; it is as easy to make a bed for asparagus as almost any other plant, and nothing pays any better for the little trouble. Set the new beds so soon as the plants can be had, giving it a generous manuring, and putting the crowns about four inches below the surface. Rows 2 feet apart, with a foot between the plants, is a good distance for the family garden, but if room can be spared the distance may be increased. Let the plants grow until the third year

before cutting. The coarse litter should be raked from the old bed, to make it smooth and clean, before the stems begin to come through the ground.

**Early Potatoes.**—The time for setting in the latitude of New York City is about June 1st, and the roots should be put in the hot-beds for starting at least six weeks previous to this. The soil of the hot-bed need not be rich, but light and loose, and well warmed. Nothing is gained by putting this sub-tropical plant in open ground until it is warm.

**Sweet Potatoes.**—The time for setting in the latitude of New York City is about June 1st, and the roots should be put in the hot-beds for starting at least six weeks previous to this. The soil of the hot-bed need not be rich, but light and loose, and well warmed. Nothing is gained by putting this sub-tropical plant in open ground until it is warm.

**Cabbages.**—Sow seeds in hot beds for medium crop; the plants from the cold frame will supply the early crop.

**Corn** is one of the *tender* plants, and should not be put in the ground until there is settled weather and warm soil for it. "Corn-planting time" varies with the locality, and good judgment must decide.

**Peas.**—See "Peas in Plenty," in the March number. Sow "Daniel O'Rourke" and "Alpha" for early, and the "Champion of England" for late; the "Champion" needs tall brush to do its best.

**Succession Crops.**—Beets, Radishes, Peas, etc., should be sown at intervals of two weeks or so, that there may be a succession of fresh "pickings" or "pullings" through the season.

**Odds and Ends.**—Try a few new varieties for the pleasure and possible profit that they may bring; but do not go into novelties largely....Keep the garden perfectly clean of weeds at the start as a weapon in the struggle against the enemy. Nothing does better execution than a heavy rake with long, sharp teeth, but it must be used early and often. Weeds that can not be killed by this are all too large.

### Flower Garden and Lawn.

Under this heading are included the various hints for the ornamentation of the grounds around the house—the *front yard* as it is generally called—with its trees, shrubs, beds, and paths, and above all the

**Lawn.**—Nothing is more pleasing than an expanse of smooth, rich, green, nicely kept grass. The lawn should be one of the features of every pleasure ground, no matter how limited in extent, and in laying out the walks and drives they should not divide the lawn more than can be helped. In making a lawn the soil should be first thoroughly manured after which, for heavy soils, Kentucky Blue Grass seed should be sown in abundance; for light soils Red-Top is best. It is well to sow the seed in two or more directions, thus securing a more even distribution, and therefore a better turf.

**Walk and Drives.**—As far as possible in laying out walks let them take a direction that all will be inclined to follow, that there may be no cross-cut "sheep-paths." The walks will need to be raked, smoothed and rolled. In constructing new ones and drives make a solid foundation of coarse stones with smaller ones above. Thoroughness in the making of a walk or drive will always pay. A good walk is a comfort while a poor one is always a source of annoyance to the owner and all others.

**Trees.**—The tendency is to plant too thickly. Young trees make but little showing at first, and over-planting is natural. For the health of the family no trees should be planted so close to the house as to exclude the light and sunshine. In planting do not copy a neighbor and thus create sameness. Do not plant large forest trees in a small yard, but select those of medium size, and attractive for flowers as well as foliage. The varieties are almost innumerable; and those from our own woods and thickets are, many times, as good as the best.

**Shrubs** planted in clumps are very useful in concealing boundary lines and giving a pleasing effect to the grounds. A well formed shrub standing alone is often very beautiful.

**Annuals.**—All hardy annuals, Rocket Larkspurs, Stocks, Pansies, and the like are to be sown as soon as the beds can be made ready. The tender ones, such as Balsams, China Asters, etc., may be sown in hot-bed or window-boxes.

**Hardy Perennials.**—Old clumps are to be taken up and divided, and it is better to reset in fresh soil.

### Greenhouse and Window Plants.

At this season the plants indoors are apt to be neglected from the press of work outside, and at just the time when they demand special care. The change of the season with its increase of heat makes the insects more abundant, and vigilance now is the price of clean plants through the summer.

**Shade** will now be required by some plants, and it can be provided by coating the glass with lime-wash, adding to the thickness as the heat increases.

**Hardening off**, or the tempering of the house-grown plants to the open air must be gradual.

**Summer Bloom.**—The greenhouse should not be stripped but made attractive through the season by blooming plants like Gesnerias, Fuchsias, etc.; sow Balsams and other annuals for pot culture.

### Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the *American Agriculturist*, from our record kept daily during the year, show at a glance the transactions for the month ending March 10th, 1880, and for the corresponding period last year:

1. TRANSACTIONS AT THE NEW YORK MARKETS.  
RECEIPTS. Flour, Wheat, Corn, Rye, Barley, Oats.  
24 d's this m'th 368,000 1,251,000 2,137,000 41,000 409,000 896,000

Since our last Review, Stock Exchange operations have been on a liberal scale, and prices of nearly all classes of securities have been on the advance, though, under a more urgent demand for accommodation, Money has been ruling higher on call, and in the discount line. Real Estate has been gaining in favor, steadily, and, under increasing purchases, the tendency of values has been upward. Dry Goods, Boots and Shoes, and Hardware have been quite active, and generally strong in price. Drugs, Dyes, Chemicals, Naval Stores, Petroleum, Tobacco, Rice, Hemp, Fish, Hops, Coffee, and Teas, have been moderately sought after, and have been variable, though the changes, in most instances, have been unimportant.

....Hay and Straw have been less freely dealt in, and closed rather easier. Metals have been less active, and quoted lower, and somewhat unsettled....Hides have been attracting more attention, leaving off stronger. Leather has further receded in price, on more liberal offerings, leading to increased activity....Sugar and Molasses have been advanced, on reduced supplies, and a livelier trade inquiry....A comparatively brisk business has been reported in Cotton, chiefly in the speculative line, at, however, irregular figures....More demands have been reported for Seeds, especially for Clover, which has been wanted by the home-trade, and has been quoted firmer....Wool has been in materially reduced stock, and active request at hardening prices. London Public Sale results favorable to holders....

A fair degree of animation has been apparent in Provisions, which have fluctuated considerably in price, leaving off more steadily....In the Breadstuff line, business has been generally quite brisk for the season—notably so in Grain, largely on speculative account, at very variable figures—Flour, Wheat, and Oats closing depressed, lower, and irregular; Corn, for early delivery, cheaper; Rye and Barley about steady. Export purchases of Flour have been recently on a limited scale. Wheat has been taken to a fair aggregate by shippers—particularly No. 2 Red, and No. 1 White—the favorites are the Winter grades, but the latest dealings indicated a downward tendency, as influenced by the favorable crop and weather reports, the adverse tenor of the foreign markets by cable, and the more urgent offerings. Spring Wheat, as having been in light stock and under strong control, has suffered least, but has been without much life as to actual trading.

Buckwheat has been taken to the extent of about 5,000 bushels for shipment—mainly to Antwerp—at from 55c. @60c., closing at 55c. per bushel. These export purchases were the first reported in our market, and were more or less experimental. About 75 tons went to Bristol, chiefly to be there sold for feeding purposes—partly, it has been stated, for Pheasants. The home trade in Buckwheat and Buckwheat Flour is about closed for the season, which, in this connection, has not been deemed a satisfactory one. The stocks of grain in store in New York harbor are diminishing rapidly. The visible supplies of Wheat,—embracing the hoards at lake ports, in transit, and on the seaboard—at latest dates, embraced about 28,035,000 bushels;—of Corn, 15,621,200 bushels; of Rye, 900,000 bushels; of Barley, 3,687,200 bushels, and of Oats, 2,909,700 bushels, against on January 31, an aggregate of 30,100,000 bushels Wheat, 13,100,000 bushels Corn, 979,000 bushels Rye, 4,155,000 bushels Barley, and 3,080,000 bushels Oats. Ocean grain freights have rallied perceptibly and more active, business closing by steam to Liverpool, 5d. per bushel; to Bristol, by steam, to 5@5½d. per bushel; to Antwerp, by steam, to 6@6½d. per bushel, and by sail to Cork, for orders, 4s. per quarter of 480 lbs.

do. do. prev's Month.....	10,877	263	1,282	25,180	29,569	

Prices for bees for the past four weeks were as follows:

	WEEK ENDING	Range.	Larger Sales.	Aver.
Feb. 17.....	7½ @ 11½c.	8½ @ 10 c.	9½c.	
Feb. 24.....	7 @ 11 c.	8½ @ 9½c.	9½c.	
Mar. 2.....	7½ @ 11½c.	8½ @ 10 c.	9½c.	
Mar. 9.....	7½ @ 11 c.	9 @ 10 c.	9½c.	

**Bees.**—The second and third weeks were dull, the receipts being much below the average for the last four months. The improvement in market for the last week is very gratifying to all interested in the live stock trade. The foreign shipments have been larger, and the demands

for home consumption have somewhat advanced the prices. .... **Cows.**—The supply has been liberal; the demand only fair, and the market dull throughout the month. Ohio cows sold at an average of \$40. .... **Calves.**—There was a fair demand for good calves, the market not being overstocked. Prime Veals were advanced  $\frac{1}{2}$  c. per pound. .... **Sheep and Lambs.**—The average receipts have been much below those of last month. Exporters have been liberal purchasers of heavy sheep, which therefore found ready sale. Prime Sheep brought 6c. Yearling Lambs, the best, sold for  $8\frac{1}{2}$  c. .... **Swine.**—The market has been quiet and steady, at \$4.50 to \$4.85 per 100 lbs. The receipts large early in the month, followed by a rapid decline.

**The Horse Market.**—The prices are low and the market dull, there being very little outside demand. A number of valuable stallions shipped for this country have either been killed or injured on the passage during heavy storms. Ordinary driving teams are selling at \$300 to \$400; stylish coach horses with good speed even reaching \$1,000 to \$1,500 per team.

containing a great variety of items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

**More Extra Pages** are again added, to meet the demands of business men who feel the influence of the renewed activity everywhere produced by the great crops of 1879, and the return to specie payments. Though with the advance in prices, the extra cost of added pages consumes much of the income from them, we prefer this to trenching upon the reading columns which are crowded with valuable information. And further, these added pages are useful to our readers, who will find many items of needed or useful information all through the advertising pages—telling what is offered, by whom, and where, and how. As often stated, one usually gets some new idea by reading what others say and how they say it.

Only *Reliable business men*, those having both the *ability and intention* to do what they promise, are knowingly admitted to these pages, and we are happy to bring such men to the acquaintance of our wide circle of active, enterprising readers. *When corresponding with our advertisers please always inform them that you are readers of this Journal. They will thus know what you expect and what we expect of them as to prompt and liberal treatment.*

#### Special Features of this Number:

The usual large variety of original articles and items on many topics is given, all of which most readers will peruse. Those too busy for this, should not omit:

The articles on **Fertilizers**. The large tables, pages 136, 137, give in very condensed form, the results of a few only of the many extensive and important experiments with fertilizers during two years past, which are to be continued this year, as noted. These experiments are, perhaps, the most valuable new contribution in our country to successful soil culture. A careful study and comparison of the figures in every line of the tables will furnish useful information. It will be well for themselves and for the country, if ten thousand of our readers embrace the opportunity offered to make such experiments the coming season. The method of procuring the fertilizers is plainly stated on page 135.

The plans and hints for the Work of the Month, pages 128, 129, 130, prepared by several practical men in the different departments, including one valuable new helper, will aid the experienced as well as the novice, jog the memory, supply sundry suggestions, and answer many questions in letters from correspondents.

Swindlers are on the "boom," and have a "he-nuff" on pages 132-3. Some Western Towns may "see themselves as others see (them)." Subscription thieves, Census cheats, etc., are noticed.

Fences and Fencing, though partly crowded this month by the Fertilizers, will afford some suggestions.

The House Plan with full specifications, on page 138, if it does not give just the plan wanted by many, will help in providing the house that is wanted.

Sheep Growers will enjoy the illustration and descriptions of the American Merino, with the important figures from Mr. Geddes, on pages 139-40.

Dairy Matters, "Gilt-Edged Butter," "Granular Butter," etc., pages 140-1, will interest every owner of a cow.

Hints and Helps to Farmers, although not all under that title, on pages 142-3-4-5, contain many items useful to one or another.

Poultry Farming, page 145, will answer many queries from correspondents and afford suggestions to others. The new Coleuses and Flowers, page 147, will interest all who grow flowers.

Everybody should have at least one Grape-Vine. How it can be grown and trained anywhere, etc., is set forth on page 149.

Market Gardeners and others will find new information on Lettuce Mildew, page 148.

Honsekeepers will of course read what a "Delaware Housekeeper" offers: the article on Cloth Mildew, etc.

The Boys and Girls are not forgotten, as they will see for themselves.

The "Basket," on pages 131-2-3-4, and 159-60, etc., with items on a great variety of subjects will be worth delving into, and supply some bits of useful information to almost to every one.

**DID IT PAY?—A True Story.**—Thirty-eight years ago, two brothers settled on adjoining farms with equal advantage as to soil, markets, capital, etc.,

One of them subscribed for the *AMERICAN AGRICULTURIST*, and now and then bought a Book or two about his own business—the whole costing an average of \$6 a year. His boys read and *thought* about their work, became interested in and *respected* it, and were happy in their toil, because *they had something to think about*. They grew up intelligent, and settled as good, prosperous farmers, respected and influential. .... The other brother (partly influenced by an economical wife) "couldn't afford papers and books" (he could afford 6 cents a day, or \$20 a year, for tobacco, beer, etc.) His boys worked sullenly by day, and "sky-larked" at night; they despised and hated their work, which for them was only exercising brute force, with little mind applied. When old enough to escape parental restraint, they quit the farm, one for this, and another for that, and *none* of them have ever amounted to any thing. He is himself a sullen, dispirited man. Six dollars a year, or even \$2 a year, would have made a wonderful difference—would have changed their whole course of life. Would it have *paid*?—Reader, choose the better way. Get your neighbors to join you, and secure some books for the use of all, through the opportunity still offered in our general premium list; or in *some* way put one or more books about their business, into the hands of your sons, from time to time, and read and talk with them about your business. It will be the best investment you can make for them.

**Prizes at Fairs.**—The custom of offering a year's subscription to the *American Agriculturist* as an award at fairs, is increasing. Some Societies have done this for several years, and we would call the attention of those who make up the schedules to the great value of such prizes. One who is awarded a dollar or two in money, soon spends the sum and forgets all about it. If instead, he has a subscription to the *American Agriculturist*, he is reminded each month of the Fair and of his success, and each time that the paper comes it gives him a hint to prepare for the next fair, and helps to sustain his interest in the local society by reminding him of its existence. Besides this, instead of small cash prizes for articles exhibited, it would be vastly better to offer in each class hooks upon the subject to which the department is devoted. Poultry books for fowls, Cattle books for cattle, a Fruit hook for apples, a Cook hook for jellies, etc.

**Manure for the Garden.**—It is too often the case that the corn field gets the best manure, and the vegetable garden must put up with that which is second class. By all means give the garden the best of the heap; that which is well rotted, and that in abundance.

**Plans of Dividing Farms by Fences.**—Any subscriber having a 200-acre farm, or one near that size, will do us a favor by sending a rough outline sketch of his arrangement of fences, showing the size, number, and shape of the lots, position of barns, lane, etc. A farm for mixed husbandry is understood, not a one-crop one.

**The Next World's Fair.**—It now looks as if there would be a World's Fair held at New York in 1883. For a while there were two, if not more, committees discussing the matter of location, concerning which there was great difference of opinion, if not of interest. As it stands now, a bill has been prepared asking Congress to incorporate a Commission for the purpose of holding the Fair, thus giving it a national character, which is to be further impressed upon it by requesting the President of the United States to notify other Governments of the Exhibition. No appropriation is asked of Congress. As the Centennial Exhibition was to commemorate the Declaration of Independence, the Fair of 1883 will celebrate the 100th Anniversary of the Treaty of Peace, and of the recognition of American Independence. The capital stock will be \$12,000,000, in shares of \$10 each.

**Worms in Peach Trees.**—"L," Waynesburgh, Pa. If your worms are those of the Peach Borer, they are not in the roots proper so much as in the trunk just at or below the surface. The borers already in the tree will come out the coming June and lay eggs for a new crop unless you dig them out, or kill them by the use of a wire. To prevent their attacks another year, bind the lower part of the trunk with stiff paper, the lower edge of which should be below the surface, and the upper edge a foot above; or make a mound of earth a foot high around the base. A few may possibly find an entrance under the paper, but they are easily discovered and killed. In the peach orchards they make a business of "worming" in spring and fall, and as they look after them regularly they do not regard the borer as a serious evil.

**The Resignation of Prof. Le Doux.**—The North Carolina papers inform us that Prof. A. R. Le Doux has resigned his position as chemist to the Department of Agriculture of that State, a loss which the resolutions passed by the Board show is greatly regretted by those best able to judge of the value of his labors.

## REMEMBER THAT Three Months REMAIN For Premiums.

April, May, and June are the three months remaining, during which *any* person who wishes to obtain one or more of the useful and valuable articles offered in our Premium List (of which a copy will be sent free to any applicant not having one). They are easily secured. This has already been done by more than **25,000** persons, who during years past have tried with success the raising of Clubs of Subscribers for our paper, and availed themselves of the liberal offers of Premiums made by the Publishers.

We invite **all** our Subscribers to take hold of this work and secure a Premium while the offer is open. Specimen copies of English or German editions will be sent to any wishing to show them for this purpose.

Premium Clubs already started can be filled up. And there is plenty of time to start **new Clubs** and complete them.

**Spring Work** is opening, and multitudes will now feel the need of the help, the hints and suggestions given by practical men in the pages of the *American Agriculturist*. They only need some one to present the paper to them and take their Subscriptions. The Premiums will well *pay* those who do this for their trouble.

**Distribution of the Carp.**—Many of our readers write to enquire how they can obtain some of the valuable newly introduced Carp, the fish which was described in our January number. The Carp is being rapidly propagated in the Government ponds at Washington, and they will be distributed as fast as they are ready. The only way to obtain them, is to make application to the U. S. Fish Commissioner, through the member of Congress from the district in which the person desiring them resides, stating full particulars

## American Grape Growing and Wine Making.

Is the title of a new work by Prof. George Husmann, of the Missouri State University. Some 15 years ago the grape "eraze" was general, books were written, nurseries could not supply plants fast enough, new varieties were offered, vineyards planted, and fortunes were made—on paper. Suddenly, in one of those peculiar reverses that no one can explain, all came to a sudden stand-still; grape-vines could not be given away, and were one to offer a new variety he would be laughed at. But amid all this general wreck, there were a few who had faith in American grapes and American grape culture; these men by no means gave them up; they have been quietly investigating the causes of failure, devising better methods of culture, seeking out better varieties both for the table and for wine, than we have ever had before, until now grape growing is in a healthier condition, on a surer basis, and promises far better results than it has ever done. Prominent among the few who have been faithful through every adversity, and whose industry has not abated, is George Husmann, who has so long been identified with grape culture in this country, and especially with that of Missouri. So great have been the changes since the flush time referred to, especially in the way of varieties, and our knowledge of them, that much in the old literature is out of date, and so much new material has accumulated that one of the demands of returning prosperity is a new work. This Mr. Husmann has given us, and all who know anything of him or of grape culture, are aware that none is more competent. This work will be ready for distribution in a short time. The work is in three Divisions, or Parts. The First Part is devoted to a description of varieties, and includes all the valuable recent additions to the list, and describes the methods of culture that he has found most successful, as well as treating upon the insect and other enemies, and showing how to combat or avoid them. Part Second gives the experience of others in the grape-growing localities in the different sections of the country, including Texas and California, with other matters of interest. Part Third is devoted to wine-making; not an elaborate treatise, but gives such practical directions as will allow any intelligent grape grower to convert his fruit into wine. The work is illustrated with explanatory engravings, and comes as a most timely and acceptable aid to the growers of native grapes. Sent from this office on the receipt of price, \$1.50.

**Value of Swamp Muck.**—Some time ago, we remarked that an acre of swamp muck of good quality, 3 feet deep, was actually worth \$25,000. No doubt such a statement is surprising. So was the statement of Dr. Lawes of England, that a ton of bran fed to cows, returned more than its cost in manure. Swamp muck, free from sand, contains 2 per cent, or 40 lbs. of nitrogen in a ton. Nitrogen is worth in the market, 25 cents a pound. So that a ton of swamp muck is actually worth \$10 for the nitrogen in it. All that is needed is to work up the muck, so as to make the nitrogen available. An acre of swamp muck 3 feet deep, contains 2,500 tons, and would require 8 months to draw out, at 10 loads a day. Few persons realize the value of the fertilizing elements of common waste matters which lie under their feet, and the innumerable tons of matter, that may be available for fertilizing purposes, and that much of the idle and neglected materials represent a vast amount of wealth.

**Cocoanuts for Hanging Baskets.**—The shell of the cocoanut is so hard and durable that it can serve an excellent purpose as a hanging basket for small plants. If cut across in the middle, a single shell will make two baskets; it is perhaps more artistic to remove one-third of the space of the shell and use the rest. The shell of itself is "rustic" and harmonizes with plants.

**Preserving Timber.**—There are several compounds used for preserving timber. The process called Kyanizing, invented by a person named Kyan, consists in saturating the timber with Bichloride of Mercury (Corrosive Sublimite). Salts of Copper have been largely employed. Creosote is now perhaps the most generally used preservative. The principle is the same in all cases: to change the albuminous matter in the wood—that part which is the most susceptible to decomposition.

**Kerosene Stains upon a Floor.**—A correspondent writes from Pilot Mound, Minn., that the breaking of a kerosene lamp has caused a "frightful spot" upon the floor, and wishes to know how it can be removed. Good kerosene has a boiling point at 350°, considerably above the melting point of lard—hence in order to drive it completely from any fabric, from paper, or from wood, it must be heated high enough to form a vapor, when, if pure, it may be completely removed. Heat may be applied to the floor by using flat-irons snf-

ficiently hot, first placing a piece of paper over the spot. It may be that after the oil is driven from the surface by heat, the stain will reappear; some of the oil remaining in the wood will be brought to the surface by capillary attraction. In such a case it will be necessary to repeat the operation as often as the stain appears.

**Muck Land.**—"W. A. C.," Ohio, has some 20 acres of land which seems to be entirely decayed vegetable matter, and he would convert it into grass land. Though it gets very dry in summer it is probable that it is very wet in spring, and that its present condition is due to an excess of moisture. Drainage is one of the first steps in reclaiming such land. If there are large tussocks of sedge, these should be cut off, dried, and burned. After a heavy dressing of lime, at least 50 bushels grass seed may be sown with a fair prospect of success, but without drainage and lime it will do little good to sow grass upon it.

**Oleo-Margarine in Iowa.**—The legislature of Iowa has passed a law, that every package of bogus butter shall be stamped "Oleomargarine" in letters not less than  $\frac{1}{4}$  of an inch in length. Whoever violates the law must pay not less than \$20 or more than \$100, or go to jail for not less than ten days or both.

## Sundry Humbugs.

As we look over our large monthly budget, we find two classes of documents "conspicuous by their absence." Not a single letter or circular showing how easy it is to make a fortune by stock speculation in Wall Street is here; formerly we had half a dozen daily. Then we find only two poor little lottery schemes from over the Canada border in place of the scores of Gift Enterprises, Distributions, Concerts, and the like. These changes are indications of the efficacy of the work of the Postmaster General in excluding all swindling schemes from the mails and the great utility of the law which gives him power to do this. But though these gigantic schemes are broken up, the minor swindles and frauds seem to be present in as great variety as ever, and show that with the return of business prosperity comes a revival of those arts which have for their object "living by one's wits," or getting money without work. The scheme which appeals most directly to us is that in which some chap uses the

### AMERICAN AGRICULTURIST AS A SWINDLING MEDIUM.

Complaints came from persons in Nebraska that they had not received the paper, and upon looking at our books no such names were found there. This occurring so many times, and the complaints all coming from the same part of the State, it was evident that there was something wrong. Upon inquiry it was ascertained that a person calling himself sometimes Jennings, and at others Stevens, had been about representing himself as our agent and obtaining money for subscriptions. He had a printed form for receipts, and the manner in which he signed these ought to have aroused suspicion, as they were sometimes signed "Orange & Judd" and again "Orange & Judd & Co." It should be known that

### WE SEND OUT NO AGENTS

to solicit subscriptions, and that any one claiming to be such is an impostor. By our system of clubs, each one who solicits subscriptions for a club does so where he is known, and subscribers know to whom they pay their money, or can readily find out his responsibility. This chap is described as a "red-headed man" who claims to have been a Quartermaster in the army. Later a letter from the publishers of the "Nebraska Farmer," at Lincoln, informed us that apparently the same scamp had been taking subscriptions to their paper, and that they had offered a reward of \$50 for his arrest. This is a form of swindling that is practised with almost every popular paper, and is one which it is beyond the power of publishers to prevent....The well known Madame Demorest, who publishes a Magazine devoted to fashions and sends out the widely celebrated

### DEMOREST PATTERNS FOR DRESSES, ETC.,

is having trouble with a woman who goes about the country claiming to act as her agent and collecting money wherever she can. Madame will give \$50 for the pleasure of sending her where the fashions do not change....

### A TOWN CHEATS A WIDOW.

The following is a fair sample of many like cases reported to us. We leave the names blank for those who

feel guilty to fill and see how it would look with their own township standing out in capital letters in the blank:

"To the Editor of the American Agriculturist.

The town of \_\_\_\_\_ State of \_\_\_\_\_ wished to have a railway constructed to bring them near market, and which would (and did) largely increase the value of the farm products. To secure the building of the railroad the town promised aid to the amount of \$50,000, or about \$2 per acre. (The land afterwards increased at least \$25 an acre all round.) Not wishing to pay the cash down, the town gave its Notes (Bonds) on 10 per cent interest. These were sent East, and on the plausible statement of agents, and having confidence in the character and good faith of the people of the town, the cash was paid for them, generally by widows and other poorer people, who having but little, wished to make it go as far as they could in the returned interest. A neighbor of mine being in poor health, sold his farm, the savings of a life of hard work, and put \$2,500 in these Bonds. He died soon after. His aged widow had those \$2,500, in this Western Town's Bonds

### AS HER WHOLE DEPENDENCE

for the rest of her days. The town, finding it not quite agreeable to pay the interest, to say nothing of the principal, got a lawyer to contest the validity of the bonds, partly on the ground that the Railroad did not quite keep up its agreement, and partly on the ground that it was "unconstitutional" for the town to issue the bonds. To enry favor with the people (voters) a Politician Judge decided against the bonds. The widow is unable to carry the case up to a higher or to a juster court. The other holders of the \$50,000 Bonds are doubtless like situated, and being widely scattered and unknown to each other, they can not combine their efforts. And so the town of \_\_\_\_\_ has coolly pocketed the \$50,000 savings, needed by widows and orphans, and while they are sitting enjoying their comforts and luxuries, these innocent contributors of hard-earned cash are thrown into penury and want. They trusted in the good faith of the people who issued those bonds and loaned money on its credit." Comment is unnecessary....Postal Cards are a great convenience, but they are largely made use of to promote various doubtful and swindling schemes. Here we have the country flooded with postal cards advertising

### THE "UNITED STATES WASHING MACHINE."

Sometimes it is "Lynn & Company," or it is "Sisson & Company," and they are "Importers and Exporters of Machinery." The parties named make a "Very special offer" to the one who receives the card, which it is, "If you will promise to show the U. S. Washing Machine, to any ten of your lady friends," they will send the machine packed and prepaid, to the person addressed; and also make terms for the sale of machines, etc. The "party of the other part," is asked to send only 75 cents, "which we have estimated will just cover the cost of packing, and the various charges to your point." This machine—so says the card, "is indeed a very remarkable labor-saving invention, doing entirely away with all the miseries of wash day"—and for 75 cents—"It will," says the card, "do the work of several women," and much more to the same effect, and all for 75 cents and a promise to show it "to any ten of your lady friends." Having great curiosity to see what kind of a washing machine could be sent to Indiana and Kansas, for 75 cents, and feeling it to be something that our readers should know about, we

### STARTED ON A VOYAGE OF DISCOVERY.

No. 36 Beekman Street was easily found, but not so easily the office of Sisson & Co. They occupy the first floor, if one begins his count from the sky downwards. The door stood open, and a man stood in the doorway. He didn't say, "Walk in," but his manner said as plainly as could be, "Keep out." The glimpse obtained of the interior was not tempting, evidently that room was as innocent of "washing," as we believe it to be of "machines." We would see Mr. Sisson. He of the door had a different view of the matter. We couldn't, as "it was after office hours."—A look at the time-piece gave 12.15 P. M. as the hour.—We would see the "United States Washing Machines,"—not much. He of the door informed us that they "did business according to a system"—one part of the "system" evidently being to keep people out of that room. Mr. S. would be back at 3.30, but it would be of no use for us to call then, as it would be "after office hours." We learned that the machines were all packed and ready for shipment, and also learned that Mr. Sisson did not care to be seen—unless indeed he of the door were Sisson himself. Our next departure was for

### "THE IMPORTERS AND EXPORTERS OF MACHINERY,"

Lynn & Co., Nos. 104-106 John Street, which, in due time, was found. No man in the door here, but within the portal was a woman, and as communicative and affable as Sisson was short and surly. Here were machines too, real washing machines. We inspected—and as we inspected we learned: that the machine was a new one; was not advertised in the ordinary way, the object being to sell through agents—some agents sell a good many,

others failed.—The machines were made in New Jersey. Stacks of letters upon a table indicated a large correspondence; there were many machines packed and ready to be sent off. We could not resist the temptation, and bought a machine—

HERE IS A PORTRAIT OF THE U. S. WASHING MACHINE!

The card says: "The machine is simplicity itself." An inspection allows us to confirm this statement. This Washing Machine is 5½ inches long, 4¼ inches wide, and 2¼ inches in altitude. There are two rollers, one handle, and two castings (one at each end), and 4 screws—"simplicity itself." The card states that the "iron parts are covered with zinc to prevent rusting"—true again, and moreover "the wood-work is made from the hardest and best seasoned timber." The handle is black walnut, one roller with an irregular surface is of ash, and the other roller is covered with

THE "UNITED STATES WASHING MACHINE."

rubber—stuck into a piece of rubber tube—does not show. The U. S. Washing Machine weighs 8 ounces, and goes by mail for 10 cents. The machine must have cost nearly 10 cents to make it, and the profit of at least 50 cents on each 75 cent trade, is very fair considering the capital invested. Their "confidential wholesale rates are \$36 per gross, which is 25 cents each." A washing machine for 25 cents! But we have omitted the

"DIRECTIONS,"—HERE THEY ARE.

"Use with any wash tub and board. Grasp the handle or rest the fingers on the cross piece, and rub the clothes backwards and forwards, pressing lightly. The friction of the corrugated rollers cleanses thoroughly. Dip the clothes or machine into the water as often as it is pressed out. When ready to rinse, roll the machine over the clothes as they are drawn out of the water."—We altogether object to that last sentence. This is a "washing machine," and you have no right to use it as a wringer, especially as a chap in Chicago makes a wringer which is much such a wringer as this is a washer. Parties calling themselves James W. Winslow & Co., and other aliases, advertise wringers at \$1.50 and \$2.50 each, which they modestly call "the best wringer in the world." Our friend Browning, President of the Metropolitan Washing Machine Co., thinking that he made a pretty fair sort of wringer in the old, well known "Universal," had a natural curiosity to see

"THE BEST WRINGER IN THE WORLD,"

and wrote to a Chicago Correspondent, to get him a sample. The Chicago man went to the advertised place, and found—a vacant lot, but after hunting with the aid of the Post Office folks, he at last found the wringers—and they are on exhibition at Mr. B's. New York office. Such a caricature upon a useful machine, we never before saw! It might help in washing, but not as a wringer, its place is under the boiler, to help boil the clothes. In the \$1.50 wringer, the rollers are a couple of round sticks, but for \$2.50 you get a thin piece of rubber over them. It is a good deal to have seen such a washer and such a wringer all in one day... It was suggested last month, that there would be various

SWINDLES PLAYED WITH THE CENSUS,

and gave a brief account of one of them.—Now comes another. Well dressed chaps visit the houses of well-to-do farmers, and leave blank forms to be filled out showing the amount of certain crops raised on the farm. The unsuspecting farmer fills out the blanks and is requested to sign it. In a few weeks the farmer is notified that his note for \$100—\$200—as the case may be, is due at such a bank. The note turns out to be made over his signature to the census paper. The census will not be taken until June, of which due notice will be given, and no doubt the officials will be able to show that they are the proper persons.... Here is more Postal Card work. This time it is an advertisement making a special

OFFER OF SILVER TEASPOONS,

by the "Tremont Spoon Company, of Boston." For 60 cents they send a set of six teaspoons. This is just 10 cents a spoon, which may be cheap or dear, according to the spoon. But it would look more business-like if the Tremont Spoon Co. of Boston, would give a street and number, and not have several of their cards, which are called "certificates" and to be returned with the order, all bearing the same number, 1723.... The most ridiculous "craze" just now is in reference to the so-called

#### ELECTRIC MEDICAL BATTERIES.

These are affairs about the size of a half dollar, made of two different metals, hung by a silk cord, and to be worn "as near the heart as possible." This thing is offered as "the most effectual and sure remedy for all diseases of the blood and nerves." What is the strangest thing about it all is, that people will believe that the wearing of the thing does them good. There is Boyd's Battery, with its "gimlet-pinted" electricity, and one apparently sincere man writes that it helped his wife when she did not know what the thing was. But then here comes one Elias, who says that "a wooden button worn upon the breast would be quite as effective as the so-called 'batteries' which have hitherto been sold as curative to an over credulous public."—That is one thing in Elias' circular that we can fully believe. But then Elias goes and makes an affidavit, and publishes it, and we will say that

IT IS A GOOD DEAL OF AN AFFIDAVIT.

It tells that there is no such chap as Prof. J. C. Boyd—that the battery of Boyd is not patented—and that his battery "was, and is, a contemptible fraud"—and ever so much more of the tallest kind of affidavit—but alas! not one word about Boyd's "gimlet-pinted" electricity.

Elias has the thing brought to the finest point. He is logical. He tells us

"THE BLOOD IS THE LIFE,"

that is his starting point, which no one can deny. Then "Electricity is the Life of the Blood"—that's not quite so clear—but we are informed that his Medical Galvanic Medal generates electricity—and there you are, what more do you want? Our medal is the only one that turns out the real sort of Electricity.—"Electricity is the Life of the Blood.—"The Blood is the life"—would you live?—Then wear our medal. All else follows, from Rheumatism to Corns. The affidavit of Elias declares that Boyd's Battery is a "worthless fraud." Yet we know an intelligent young lady who can feel the electricity as soon as she takes it in her hand! One druggist in a small town sells several of these batteries every week, and the buyers are sure they are benefited. There is a pitiable popular ignorance about electricity, and an equally pitiable readiness to believe whatever is said about it. The idea that any combination of metals worked up into a medal and placed upon the skin, can have any effect upon the body in general, is simply absurd. Still it is asserted, and people like to believe it, just as some otherwise intelligent persons believe that carrying a Horse Chestnut in the pocket will keep off rheumatism.... Last month we stated that a person was cutting a big swath in the doctoring field in Ohio, and claiming to be from

THE GREENLEAF MEDICAL INSTITUTE

of New York City. We hinted at the remarkable modesty that refrained from giving the street and number of a remarkable Institute, that could send out such a remarkable doctor as Dr. Greenleaf, the son of his father. Now we get the fellow's circulars from Davenport, Iowa, and these read: "Greenleaf Medical Institute, No. 648 Broadway." To be in New York City several hours daily, and not know about such an Institute, was a state of ignorance not to be endured, and so soon as we had the number we started from 245 for 648. So far from finding any sort of a Doctor's shop.

NO. 648 IS THE ST. CHARLES HOTEL!

The clerk of the hotel had never heard of Doct. Greenleaf or his Institute. As the most likely means of learning about such a chap we inquired of the policeman of that beat. He knew nothing of Doctor Greenleaf or his Institute.—Yet the honest people of Ohio are running after and paying money to this pretender—even the press helps him with favoring notices.—To judge from his circular, we do not think that the fellow is any more of a doctor than the St. Charles Hotel is an "Institute."

**Early Strawberries.**—The first arrival of strawberries from Florida, was about the first week in Jan., and since then the market has been well supplied. We have kept the run of the fruit that has been offered, and have been surprised to find that the variety reaching market in the best condition, is Charles Downing, a berry generally regarded as too soft for transportation to great distances. The fruit from Florida makes the greater part of the journey by steamer in a refrigerator, and, as a general thing, arrives in excellent condition. While some varieties, like the Wilson, become dark colored and dull after they have been picked for a day or two, the Charles Downing remains as bright and lively in color, as if just from the vines—a most valuable quality in a market fruit, and especially in one for shipping.

**The Great Dog Show.**—The exhibition of the Westminster Kennel Club, has become an established institution, and is looked for with the crocuses. This year the show will be held on the 27th, 28th, and 29th of the present month, the entries closing on the 12th. We recorded the great success of last spring's show, but the managers

think the coming one will excel all former exhibitions in attractiveness. As in former years, Madison Square (formerly Gilmore's) Garden, will be the place.

(Basket Items continued on page 159.)

#### Bee Notes for April.

BY L. C. ROOT.

In most locations bees will be placed upon their summer stands during the present month. At this season of the year great care should be taken to give the bees every advantage and encouragement to increase in numbers. After they have had an opportunity to fly freely, the hives should be examined and thoroughly cleaned. A good way to do this is to start with a clean, empty hive, and place it upon the stand of the first hive to be examined, having the one containing the bees directly in the rear; lift the combs from the old hive and place them in the new one. After cleaning the hive from which the bees have been taken, pass to the next, and transfer from that into the first hive, and so through the yard. When handling the hives, be sure that each colony has a laying queen, and plenty of honey. Let there be only a sufficient number of combs for the bees to occupy. Carefully open the hives in the morning, when the bees are compactly clustered, and remove those combs not occupied by the bees. This will allow those inexperienced to decide the proper number of combs to leave. The combs that are thus removed from the hives should be cared for, and kept in a dry place where mice or rats will not have access to them. If any colonies should be found queenless, unite such with the lightest stocks that have good queens. After the bees have had an opportunity to fly for a day or two, the presence of a queen may usually be ascertained by the presence of eggs in the combs in the center of the cluster. When the number of frames is limited, have a good, close fitting division board at the side of the combs to diminish the space which the bees must keep warm. Contract the entrance to the hives, and be sure that all upward ventilation is prevented. All this should be done in the middle of the day when it is warm. Care must be taken not to expose combs, or in any other manner to induce robbing. After bees are put in proper shape do not make the mistake of opening the hive too often until the season is sufficiently advanced. Handling bees too early, to stimulate breeding, often results greatly to their injury. As the season grows warmer, and the bees increase in numbers, combs may be added.

ANSWERS TO CORRESPONDENTS.

**SIZE OF BOXES.**—"What is the most desirable size for section honey boxes?".... This subject is receiving much attention of late. It was discussed at the session of the North Eastern Bee-Keepers' Association, recently held at Utica. The sizes that are the most used at present are 4 by 4 inches, 5 by 5 inches, and 5 by 6 inches. The honey dealers of New York have decided in favor of the medium size, which takes 5 by 5-inch glass, and weighs about 1¾ lb. when filled with honey. Two inches is the proper width.

**MRS. COTTON'S METHOD.**—A correspondent writes: "I have received a circular from Mrs. Lizzie E. Cotton, in which she claims large yields of honey, if we will adopt her hive and system of management. Is it reliable?".... The numerous inquiries in reference to the above mentioned circular, make it necessary that we should give our views. One with but a slight knowledge of matters relating to bee-keeping should be able to see at once that the statements in this circular are not reliable. For the benefit of those who are uninformed, we would say that we have known of this Mr. Cotton (it is said that it is he who sends the circular) for many years, and regard his claims as to his hive and his statements as to the management of bees as thoroughly unreliable. Whoever is induced by the statements of this circular to commence bee-keeping, will be sure to meet with great disappointment.

**COMB-FOUNDATION.**—One correspondent asks: "Do you advise using comb-foundation in honey boxes. How

large should the piece be, and how do you fasten it in the box?".... A Foundation is now made which is so very light that it is not objectionable in the boxes. Make the guide for each comb of the width of the box at the top, and let it come to a point at the bottom, as shown in the engraving. Some advise a piece of the full size of the box. Whatever the shape, it should reach to within about three-eighths of an inch of the bottom of the box, so that the bees can reach it. I use the best white glue to fasten the foundation in the boxes.

**BROOD FRAMES.**—"Do you advise filling brood frames with comb-foundation before hiving a swarm?".... If you use foundation in which wires are incorporated to prevent sagging, its advantages cannot be over estimated,

as you can thus secure straight worker combs throughout, and the hive will be filled sooner than without them.

## Fences and Fencing.

### Fencing Letters Unanswered.

It is simply impossible to reply individually to many hundreds of letters—at least a bushel of them—asking specifications as to cost of iron fence, lists of manufacturers, opinions of this and that particular variety, the value of this or that old or new form, whether this or that new form is patentable, what we think of it, etc., etc. The best we can do is to read over what is received and prepare for these columns such materials as seems to be most worthy of publication for general information.

### But more Letters are Wanted.

We want many more letters from those who have used barbed wire fencing for a year or so, telling plainly the present opinion of the user, in regard to its value, its dangerous character or otherwise, whether the user will put up more and advise others to do so or not, what kind is used, and any other items in the same line; and we desire to know in each case whether the writer has any direct or indirect interest himself or through friends, in the sale or manufacture of any kind of fencing. Several letters have come strongly recommending one kind or another, which have upon investigation been found to have come from *interested* agents, whose opinions are necessarily colored by such interest.—We have not the slightest interest in any one kind over another, and neither sell nor supply any kind.—Our only business is to collect and supply information that may be most useful to all our readers, and to promote investigation and improvement. These last remarks are made necessary by the receipt of numerous letters saying: "Send me your circulars and the cost of (this or that amount) of fencing"—letters doubtless written by those who only learned through other journals that we are giving special attention to this subject.

**NOTE.**—In describing the iron post, fig. 27, on page 92 last month, it was credited in some of the first copies to Phillip S. Justice. It should have been Abram G. Powell & Co., Philadelphia, and was printed correctly in the later issues. The advertising pages gave the manufacturer's address.

### Weight of Iron Posts by Measuring.

A solid or cubic foot of water at ordinary temperature (62° F.) weighs 62½ lbs. avoirdupois, and 27⅞ solid inches (27.643) weigh 1 lb. Wrought iron has a specific gravity of 7.645 to 7.817—average say 7.731, that is, it is about 7¼ times as heavy as water. Therefore a trifle over 3½ solid inches (or 3.575 solid inches) of wrought iron weigh one pound. Examples: A bar of iron 1 inch wide, one-half inch thick, and 6½ feet (78 inches) long, contains 78x1x½, or 39 solid inches. Adding 4 cyphers to the right and dividing by 3.575, gives the weight of such a bar in pounds and tenths, that is 10.9, or 10⅞ lbs. A wrought iron bar 6 feet long, 1½ inches wide, ½ inch thick (72x1½x½), equals 27 solid inch, and 27.000÷3.575 equals a little over 7.5 or 7½ lbs. Cast iron is nearly one-eighth lighter than wrought iron, say 13 per cent less.

### A Wisconsin Farmer's Talk About Fences.

To Editor of American Agriculturist:

I wish to say a few words with regard to the "Barbed Wire Fence" question. With all the figuring on this point, I find no showing describing how it is possible to build a *lawful* fence with wire. It would be a grand thing for the country if this could be done, but it can not unless 7 to 10 wires are used. Even then I doubt whether it would turn pigs, and any fence that won't do that, is not the thing for a majority of farmers to adopt.—I could give you facts and figures to substantiate what I say, but do not wish to be tedious. I own a snug little farm of 82 acres here, and I have at least ten different kinds of fencing on my place, "Barb Wire" included, so I know of what I speak. Whenever any man can show me how to build a wire fence that will be pig-proof, then I will adopt the plan, even if it cost one-half more to construct it, for in the long run it will be much cheaper than

wood fences. Meantime, we must be content to get along the best way we can.

### A GOOD FENCE

can be constructed in either of the following ways—fence-boards 16 feet long; posts 8 feet apart:

3 boards and 2 wires.	or 3 boards and 2 wires.
3½ inches to first board.	3 inches to first board.
6 inch fence-board.	6 inch fence-board.
3½ inches to second board.	3½ inches to second board.
6 inch fence-board.	6 inch fence-board.
6 inches space.	5 inches to third board.
6 inch board.	6 inch board.
10 inches to first wire.	9½ inches to first wire.
13 inches to second wire.	13 inches to second wire.
54 inches total height.	52 inches total height.

The law in this State (Wis.) requires fences to be 4½ feet high, or 54 inches, but I would be willing to risk a wire fence 50 inches in height, thus: 50 inches to top wire, 37 inches to next, 27 inches to next, 19 inches to next. The bottom space of 19 inches left can be managed this way: Make portable pieces of fencing by nailing two 4-inch wide fence-boards on to stakes, and driving them down at bottom; they can be taken up at pleasure. True, a fence of three or four wires will do for cattle and horses, and may be a good thing out in Texas or Colorado, and other Western States and Territories, but for general adoption it is not the thing, because you can not construct a perfect or lawful fence with it. As to the present forms of barb wire being dangerous to stock, I have only to state that whoever says so, does not know what he is talking about. I have two horses that stick their heads over and between the two top wires of my fence, only 11 inches apart, and crowd them down and reach at least a foot on the other side the fence, and eat the crop close to the ground, and I have seen cows do the same, and I use the Fren-tress Wire, which is, perhaps, the severest kind manufactured.

There is not a single form of Barb Wire at present in use that is half *barbarous* enough. My stock have never received the least damage from the wire, and I don't believe they ever would, were the barbs ten times as severe, in fact we need a more severe barb wire introduced, and then we may hope to make a pig-tight fence by putting 3 or 4 wires pretty close together at the bottom of the fence.

ROBERT WOOD.

GRANT COUNTY, WIS., March 1, 1880.

We give the above as a sample of several letters from intelligent men. Others express themselves equally strong against the use of barbed wire, as *barbarous*, as dangerous to horses, cattle, and sheep, as having "the barbs festooned with wool picked from sheep, etc." One of the most frequent objections we hear just now is, that in plowing up to barbed fences, either along side of them or at the head-lands, the team has to be kept at such a distance that there is almost as much waste land as in the use of the "Virginia" or "worm" rail fence.—Thus far, the opinions are so contrary and so nearly equally divided, that one is at a loss what to decide, and we urgently invite further correspondence as stated above. The fact that serious injuries have resulted from the use of long barbs is not set aside by the statements of others that they have experienced no trouble. The question to be decided is: Is the danger to animals, and are the objections on account of working up close to them, their tearing of garments, etc., sufficient to militate against their advantages? It is contended by their advocates that unless the points are both long and sharp, they will be little more feared and be but little more effective, if any, than the old plain wire; that animals eager to reach good feed will not be stopped by anything short of rows of sharp spears that will pierce to the quick. There is a good deal of force in this statement, more than we were ourselves at first disposed to concede. But our position has been, and is, that of an unprejudiced and, personally, uninterested collector of information, a learner in behalf of our readers and the public.

We have a farm needing new fencing, but we are still patching up the old fence, partly because the collected experience is *not yet* sufficient to enable us to decide upon the best kind, and partly because new forms and new devices are being called out by the agitation of the subject, and we are hoping to

find something better than has yet been brought before the public, both for posts and for the running fence. We are convinced that a good fence, both posts and wire or straps, made of steel or iron, or both, is far superior to wood as respects durability and freedom from repairs; that a metal fence thoroughly protected against corrosion will be cheaper in the end, at double the cost of wood—except in the few localities where locust, red cedar, and chestnut timber are abundant and cheap.

As previously stated, the very recent "boom" in the prices of iron and steel, amounting to fully 100 per cent, has temporarily checked and delayed the general adoption of these materials for fencing and especially for posts. Still, the cost of the raw material being only a comparatively small part of the running fence, exclusive of posts, the advance in cost of wire has not been so great as to prevent its pretty general adoption. Indeed it is indispensable in many parts of the country, because of an absolute lack of wood on the spot, and the large cost of its transportation, while lumber itself has risen in value very materially. The supply of iron and of steel is unlimited—the earth's surface is full of it, so to speak, or at least the deposits of iron ores are inexhaustible, and the processes of reduction and manufacture are being constantly cheapened by new discoveries and inventions.

The present high prices are merely the result of a temporary sudden great demand. Iron and steel can be profitably produced far below the present selling rates, and the demand will be met by increased production, so that we shall in the near future be able to obtain them at perhaps as low rates as before the recent advance. In the meantime, while continuing to use metals for new fencing, the country will be ready with improved forms of posts, to use iron and steel as the chief fencing materials, as soon as prices become normal.

### A Choice as to the Length of Barbs.

In corresponding with manufacturers, at least two leading establishments express to us a readiness to meet the wishes of purchasers, by providing barbs of any length or *shortness* and *bluntness* that may be desired, and we presume most others will do the same. They nearly all assert that the prevailing present demand is in favor of long and sharp barbs. As we have already stated, the use of long and sharp barbs will not be submitted to by the public if placed upon fences along traveled highways, and anything that can catch and tear garments, or scratch the human skin must be absolutely prohibited where, in village or country, the margins of the public streets are used as sidewalks. We doubt if legislative enactment will be or should be made to prevent anyone from erecting his interior fences as *barbarous* as he may choose—except where Mr. Bergh and his humane co-workers may interfere in behalf of the dumb animals. Any barbs having a hooked form should be rejected.

Fig. 28 comes from "Citizen," Philadelphia, who has known this form used successfully for ten years past. The base piece is made of cement and gravel by the farmer himself, one barrel of Rosendale Cement, with fine gravel, sufficing for about 35 of the bases. Diameter of bottom, 14 inches; height, 13 inches. (These dimensions can be larger or smaller, according to the looseness or firmness of the soil). An opening in the top 5 inches or so in depth

Fig. 28.

The bar can be notched or pierced for attaching the horizontal wires. If made of steel, it can be of smaller size. Such a post may be usefully employed in many locations, but digging the large holes required to receive the wide base would be objectionable for extensive field fencing. The depth re-

admits an iron bar, say one inch wide, half-inch thick, and three feet, or more, high. The bar is fastened in by pouring around it melted sulphur. "Citizen" says it stands so firmly, that he has seen the bar bent nearly to the ground without disturbing its base fastening.

quired, however, is only half that needed for smaller bases, and there would be no lifting by frost. At \$1.75 per barrel for cement, and with gravel at hand, the outlay for 35 bases would be 5 cents each. A wrought iron har 1 inch wide, half-inch thick, and four feet long, weighs about 6½ lbs.

### Important to Every Farmer.

#### The American Agriculturist Farm Experiments to be Continued.—A Key to Valuable Knowledge Placed Within Reach of All.

All the talk about "Progressive Farming," "Improved Agriculture," "Science Applied to Farming," has two objects; the increase of the farmer's knowledge and of his crops. If a farmer must invest \$19 to get \$20 of increase from a field, it is poor science, and poor farming; but if by investing \$5 on a field the increased crop brings him \$20, then "Science Applied to Farming" pays, and it pays him to know the reason why.

#### There are Some Settled Points in Agriculture.

Among these are: 1. All soils, excepting of course the virgin ones of the newer States, for profitable culture *must* be manured. 2. The larger the crop upon an acre, the cheaper per bushel, ton, etc., should that crop be raised. 3. In our ordinary farming no farmer makes all the manure that he could profitably use upon his farm. 4. The main value of manure (stable or yard-yard) depends upon certain constituents, and these may be had in other forms; in artificial or chemical fertilizers. 5. All soils do not alike need the same fertilizers. 6. It is a well established fact that while it will pay the farmer to buy the fertilizers his soil needs, it is a waste of money to buy and apply to his soil, constituents of which it already has enough. The question will naturally follow—

#### How Can We Find Out What the Soil Needs?

It is to help every farmer to answer these questions: "What does my soil need?" "What fertilizer can I buy that will pay a profit in crops?" that the *American Agriculturist* Experiments were instituted. These experiments were begun in 1878, and were continued last year. Several results were given last month, and this month we present on page 136, in a tabulated form, an array of facts that will convince the most sceptical that

**The Right Fertilizer in the Right Place** will pay. And not only pay, but the profit on the investment is often such as to help answer the vexed question: "Will Farming Pay?" These results were obtained by just such men as you, "Farmer A," or you, "Farmer B," on just such farms as yours, and by just such means as are within your reach. These men are farmers, like yourselves.

Now there are thousands, yes, tens of thousands, of just such men as these all over the country; every township, every neighborhood, has one or more readers of the *American Agriculturist*, who would have the same knowledge of their own fields that these farmers have of their soils. If these farmers knew that it would *pay* to buy Potash, or Phosphoric Acid, or Nitrogen, they would buy it, but they can not afford to run many risks. It is evident that every one of these experimenting farmers now knows better, to a certain extent,

**Just What He Wants and Does Not Want** to put upon his land this year. Not a farmer who reads this but would gladly give \$5 or \$10 to know as to his farm what these people know as to their's. There is no way in which this information can be had so cheaply and so certainly as that by which these farmers acquired it. They asked the soil, and

#### The Soil Responded.

The questions were in the bags of the AMERICAN AGRICULTURIST FERTILIZER EXPERIMENTS. The results obtained last year are so valuable, not only to the experimenters themselves, but to agriculture generally, that we propose to

#### Continue the Experiments in 1880.

While changes, and it may be some improvements might be suggested, yet for the sake of uniformity

and to prevent all mistakes, the methods and plans of last year will be unchanged for 1880. The same fertilizer in (with one exception) the same sized parcels, will be sent out with the same directions, at the same prices, and by the same dealers, though the prices of some materials have so advanced that it will be done at a loss.

#### The Manner of Conducting the Experiments

was given in full in the April No. of last year, and will be explained plainly and in detail in the directions that accompany the fertilizers. We need only here give a general idea of what is to be done. Those who consult the article given in April last will find that *three* sets were offered, for one fourth, one half, and one acre, respectively. The offer this year is the same in every particular, except in the omission of the first, or quarter acre set. Very few called for that, and the area of land being too small for satisfactory results we now offer but

#### Two Sets of Experimental Fertilizers.

Viz.: Set No. 2 for half an acre, cost \$5, and Set No. 3, for one acre, cost \$8.30. It is thought better to avoid all confusion to continue the *same numbers* (2 and 3) for these sets that they bore last year, omitting No. 1. In order to insure uniformity in the fertilizer furnished by the several parties who have agreed to supply them, the publishers have stipulated that samples shall be analyzed by Prof. Atwater, and that they shall in every case be satisfactory to him as to quality. Full directions for making the experiments will be furnished with the fertilizers, and also blank forms for recording the results. The farmer who orders this half-acre set will find it labelled thus:

#### AMERICAN AGRICULTURIST FERTILIZER EXPERIMENTS, 1880.

##### No. 2—Half Acre Set.

Cost of Set of Fertilizers, in bags, shipped, \$5.00.

This will consist of *eight* bags, A, B, C, D, E, F, G, H, which are to be used on eight plots, two being left unmanured for comparison. Bags A, B, C, contain Nitrogen, Phosphoric Acid and Potash, singly. Bags D, E, F, contain these constituents in twos. G, contains all three together, and H, contains *Plaster* only.

#### EIGHT RODS.

* TEN RODS—each Plot one Rod wide and Eight Rods long.*	Plot 0....	
	No Fertilizer; for comparison.	
	Plot A....Nitrogen.	
	Bag A, containing 10 lbs. of Nitrate of Soda.	
	Plot B....Phosphoric Acid.	
	Bag B, containing 15 lbs. of Superphosphate.	
	Plot C....Potash.	
	Bag C, containing 10 lbs. of Muriate of Potash.	
	Plot D....Nitrogen and Phosphoric Acid.	
	Bag D, { containing 7½ lbs. of Nitrate of Soda. mixture of 15 lbs. of Superphosphate.	
* TEN RODS—each Plot one Rod wide and Eight Rods long.*	Plot E....Nitrogen and Potash.	
	Bag E, { containing 7½ lbs. of Nitrate of Soda. mixture of 10 lbs. of Muriate of Potash.	
	Plot F....Phosphoric Acid and Potash.	
	Bag F, { containing 15 lbs. of Superphosphate. mixture of 10 lbs. of Muriate of Potash.	
	Plot G....Nitrogen, Phosphoric Acid, Potash.	
	Bag G, { containing 7½ lbs. of Nitrate of Soda. 15 lbs. of Superphosphate. mixture of 10 lbs. of Muriate of Potash.	
	Plot H....Plaster (10 lbs.)	
	Bag H, to learn the effects of this fertilizer.	
	Plot 00....	
	No fertilizer; for comparison.	

#### How to Use these Fertilizers.

Select a piece of uniform soil, as nearly like the rest of the field as may be. It can be marked out in any field prepared for a crop. It should be nearly level, so that one plot will not receive the washings from another. When plowed and harrowed well, mark off with stakes, in 10 plots, as shown in the above diagram; one plot for each bag, and calling them as here indicated.

Here you have the first and last plots marked 0 and 00, while the others are one for each of the eight bags, which are marked with the same letters. Sow each bag uniformly over its own plot; that is, bag A, on plot A, etc. (the fertilizers are all finely ground and dry).—Harrow the fertilizers well into the soil, running the harrow lengthwise of the plot, taking care to confine each fertilizer to its own plot. Then plant or sow corn, potatoes, or any other crop over the whole, the same amount on each plot, running rows lengthwise of the plots, and cultivate and treat the whole alike during the season. N. B.—Those who wish, can divide the whole plot across into halves, planting, say, corn on the left-hand half and potatoes or other crop on the right-hand half, so that each crop shall extend across the fertilized strips. It is important to select worn out soils for soil tests, that is, those having only their "natural strength," and little or no richness left from former manuring. The soil must be uniform, or the tests will mislead.

#### What the Experiment will Tell:—

FIRST: By watching the growth, and measuring the gathered crop, it will be easy to see how the crop on that soil is affected by Potash, or by Nitrogen, or by Phosphoric Acid, or by combinations of them.

SECOND: By comparing each plot with the no fertilizer plots, 0, 00, it will be easy to see which fertilizer pays expenses, or the greatest profit.

THIRD: Such an experiment will be interesting, will stimulate thought, and prepare for more extended investigations. If there are boys on the farm, it will awaken interests in their minds, and be a good agricultural school, on a small scale, at home. The Pamphlet sent with each Set will greatly help in this.

FOURTH: It will be a good step towards helping each experimenter to decide for himself, and for his neighbors, *what* fertilizers, if any, they can go into more largely in the future.

Of course a single trial will not tell the whole story. The trials should be continued through subsequent seasons. This is not a royal road to knowledge, but it is a start in the right direction.

NOTE.—It will be a good plan to add other similar Plots, and apply on them severally, stable manure, lime, and any other fertilizer at hand, for making a comparison.

The above is very simple. The bags are all of accurate weight, with standard fertilizers of known quality and composition, and all the experimenter has to do is to mark out the plots, and use the bag marked for each plot. The result in the growth and in the yield will indicate what each fertilizer will do, on any soil for the crop or crops grown, also what any two of them will do if used together, and what all will do used together. The different materials in each bag are thoroughly mixed and prepared, so that they have only to be sown without further mixing or care.

The Second Set is for one acre, and is marked:

#### AMERICAN AGRICULTURIST FERTILIZER EXPERIMENTS, 1880.

##### No. 3—One Acre Plot.

Cost of Set of Fertilizers, in bags, shipped, \$8.30.

This is the same as No. 2, except that the quantity in each bag is *doubled*, for plots of double size (one-tenth acre each). As the expense for bags, putting up, shipping, etc., will be the same, for each set, the double amount of fertilizer put in will cost only \$8.30, instead of \$10. With the larger plots, more valuable results will be obtained, and more than one crop can be tried. The expense of the fertilizers, \$8.30 per acre, will very likely be more than returned in the increased crop on a part of the plots. We strongly advise all to try Set

PRODUCE, INCREASE, AND GAIN OR LOSS PER ACRE

† Including market price plus \$5.00 per ton for freight.

We have only to ask that each farmer study carefully the directions and the Pamphlet accompanying each set, that he may have a clear idea of what he is expected to do in order to make his experiments useful to himself, and consequently, to others.

To the experimenters of last season we especially urge the importance of repeating the trials through

## Science Applied to Farming—LVI.

### General Results of the Farm Experiments.

The Table on page 136 gives examples of the experiments with fertilizers in 1878 and 1879, and the one on this page general averages of results. I commend their study to all thoughtful farmers.

1. It must be remembered that the trials were not only subject to all the vicissitudes of weather and season, but were made on soils of all sorts, but mostly very much run down. The directions were to select worn out soils. Hence the average results with a given crop do not fairly represent what might be expected on soils adapted to its growth and in average condition.

2. As would be expected, the results of the two seasons agree in the main, though with the less favorable weather of 1879 the crops averaged less than those of 1878.

### The Effects of the Different Fertilizers.

3. The "Complete Chemical Fertilizer," the mixture of 300 lbs. Superphosphate, 150 to 200 lbs. Potash Salt, and 150 lbs. Nitrate of Soda, costing \$15.38 per acre (including \$5 per acre for freight), brought the largest crops, excelling even the farm manures with all the crops on which the number of experiments is large enough for a fair comparison. But it must be remembered that this mixture was proposed to test soils and not to bring large yields, and does not show how well chemical fertilizers may do. The "complete fertilizers" prepared by reliable dealers for special crops, are of course more appropriate for them and would give better results than the mixture.

4. The mixture of superphosphate and potash salt, costing \$9.25 per acre, brought a trifle less corn and decidedly more potatoes than farm manures.

5. The mixture of nitrate of soda and superphosphate, which corresponds closest of all to the ordinary ammoniated superphosphates, fish manures, and guano, though costing more than the mixture of superphosphate and potash salt, brought less increase of corn, potatoes, turnips, sweet potatoes, and indeed of every crop but oats. The number of experiments with oats, however, is too small for any general conclusions. It is very probable that they and the cereals generally would be more helped by nitrogen, and less by potash, than the other crops. But it is a question whether manufacturers of ammoniated phosphates would not do better to substitute potash salts for the nitrogenous materials in compounding their fertilizers, at least for some crops. The mixture of nitrate of soda and potash salt the least efficient of all.

6. As to the efficiency of the materials separately, the nitrate of soda by itself was seldom of much use, the sulphate of lime was frequently, the muriate of potash very often, and the superphosphate generally profitable. Doubtless considerable of the effect of the superphosphate was; in many cases, due to the sulphuric acid and lime.

7. As to the effect of ashes, the results are variable, though generally they were efficacious.

8. One of the chief defects of these experiments is that so few parallel trials with lime were made. There are many cases in which a dressing of lime is the cheapest and best means of improving the land.

### Artificial Fertilizers vs. Farm Manures.

9. Not only did the "Complete Chemical Fertilizer" bring a larger average increase than farm manures as actually used; and the mixture of superphosphate and potash salt nearly as large average increase, but the quality of the crop was generally better with the chemicals than with the farm manures. Potatoes, especially, were finer in quality and less disposed to rot with the artificial fertilizers than with the farm manures.

### As to Mode of Applying the Fertilizers, Whether Broadcast, or in the Hill or Drill.

The results are on the whole against applying in the hill or drill. The best results in the majority of cases came when the fertilizers were sown broadcast. Several of the very best were where the materials were scattered over a strip a couple of feet or so wide along the rows. Many of the worst re-

sults came when the fertilizers were put in the hill or drill. The nitrate of soda and potash salts thus applied often injured the crops, especially in dry weather.

### Effects of the Fertilizers on Different Crops.

10. Potatoes and turnips responded most profitably to the "Complete Fertilizer," in nearly every case. Corn, on the other hand, was largely helped by the superphosphate and potash salt, but received little benefit from application of nitrogen in any form.

### The Feeding Capacity of the Plants.

11. The experiments imply that the Corn was some how able to gather nitrogen from natural sources, provided it had enough of the mineral ingredients at its disposal. They do not tell how much of the nitrogen came from the roots of the preceding crops, how much from other nitrogen compounds in the soil, and how much from the air. They imply that potatoes possess in far less degree than corn the power of gathering sufficient supply of either nitrogen or the other ingredients of its food from soil and air. They imply that turnips are generally unable to obtain enough phosphoric acid from the soil, and are greatly helped by it in fertilizers; that without its application they usually get but little good from other materials; that with it alone they can generally gather but a partial supply of the other materials of their food; and that for a full yield considerable quantities of all the soil ingredients of plant food are needed close at hand and in available forms. But except on corn and potatoes these experiments are still too few for reliable data.

### The Best Fertilizers for Different Crops.

12. The most profitable material in a given case is that which is best fitted to its needs. The chief factors of the problem are: *first*, soil; *second*, season; *third*, feeding-capacity of the crop, its power to gather its food from soil and air; *fourth*, form of combination of the ingredients of the fertilizers; *fifth*, the indirect action of the fertilizer.

Soils vary in respect to the plant food they supply in available forms. Phosphoric acid is most often deficient; next come potash and nitrogen; then, lime and sulphuric acid, and rarely magnesia. But the infertility of soils is due to physical causes perhaps nearly as often as to chemical. Soils often do not have the proper texture, they are too compact or too loose; or they lack absorptive power, they cannot retain the plant food until plants use it but suffer it to be leached away by drainage water; or the moisture supply is bad, they are too wet or too dry. These defects are as fatal as lack of plant food. Many soils need amendments first and then manure. Drainage, irrigation, tillage, use of lime or muck are often the cheapest if not the only means for bringing up poor soils. Season counts for much, often for everything, in the action of manures.

The effects of the forms of combination of the ingredients, i. e., of phosphoric acid in bone as compared with superphosphate, of potash as sulphate

### Averages of Results of Experiments of 1878 and 1879.

Produce, Increase, and Gain or Loss per acre, with different Fertilizers and Crops.

\* As calculated by the experimenters by subtracting the cost of fertilizers, freight, and applying, from value of increase over no manure. † Loss.  
‡ Including only those in which farm manures were tested with the chemical fertilizers.

vs. muriate, were not tested. Nitrogen in different forms was used in some special experiments with, on the whole, the best results from Peruvian guano, next from a mixture of nitrate of soda, sulphate of ammonia and dried blood, and the worst from these last separately. As to the indirect action of fertilizers in improving the texture of the soil and setting its plant food free, the experiments have nothing to say, but we know that it often makes a large part of the usefulness of the fertilizer.

13. Leaving differences of soils out of account, and considering the average results of the experiments; the best among the materials used to produce large crops of Corn would probably be a mixture of Peruvian guano and potash salt, with perhaps the addition of some fine ground bone or superphosphate. The most profitable mixture would probably consist of muriate of potash with either superphosphate or fine ground bone, or both. In a number of special experiments on corn a mixture of 300 lbs. of superphosphate and 150 lbs. of muriate of potash, which can be bought in the larger markets for \$7.50 to \$3.00, brought on the average 50 1/2 bushels of shelled corn per acre.

14. For Potatoes, which responded well to all the materials, probably a mixture of Peruvian guano, or fish with potash salts would be generally profitable. For either corn or potatoes, nitrate of soda, sulphate of ammonia, dried blood, or better, a mixture of these, could be advantageously used to supply the nitrogen, and superphosphate or bone-dust or a mixture of the two, for the phosphoric acid.

15. The common impression among farmers that the best use of artificial fertilizers is to supplement farm manure is doubtless, in ordinary circumstances, correct. The right way is to make the most and best manure that is practicable upon the farm, and piece out with such commercial fertilizers as experiments and experience prove profitable.

16. I derive no formulas for fertilizers from these experiments. There are many cases in which complete fertilizers are in place and many more in which the farmer does not know what his soil and crops need.

Middleton, Conn.

W. O. ATWATER.

### A Farm House Costing \$1,500.

BY S. B. REED, ARCHITECT.

These designs are for a substantial country dwelling, arranged to meet the requirements of farmers in moderate circumstances, and give as much accommodation and convenience as can well be done for the sum named. [This design, which was made

Fig. 1.—FRONT ELEVATION OF HOUSE.

to meet certain requirements, has many excellent features, but were we to build such a house we should, instead of the limited porch, run a broad veranda or piazza across the whole front. Were this done, the space now occupied by the porch could be thrown into the Hall or Entry, which, in a country house, is often one of its most useful rooms. This of course would add a little to the expense, but would be money well invested.—Eds.].....**Exterior** (fig. 1).—The extreme ground measurements are 30 by 40 feet, giving a breadth becoming its relation as a farm house, with the surrounding grounds. The Foundations show 2 feet above the earth grades. Unless the site is already very high, the earth taken from the excavations should be used in raising the surface of the grounds at least one foot immediately surrounding the foundations, so as to turn away all

Fig. 2.—THE CELLAR.

water, and also to give increased height and better appearance to the whole building. The simple methods shown in the treatment of the porches, windows, cornices, gables, roofs, and chimneys, give the whole a rustic appearance quite in accord with its domestic intent....**Cellar** (fig. 2).—

Height, 6½ feet; dimensions same as first story, giving abundant cellar room, which may be divided into separate apartments for vegetables and other uses. If there is a porous or sandy bottom, and proper ventilation, it will be sufficiently cool and dry for keeping fruit with good success. Six small windows built in the walls, afford light and ventilation to all parts.

An opening in one of the flues of each chimney will carry off unwholesome vapors when the windows are closed in winter. There is an outside entrance under the rear porch, and an inside stairway leading to the rear entry on the first floor, with a door at the top. This location of cellar stairs prevents cellar odors and dust from coming by them directly into the body of the house....**First Story** (fig. 3).—Height of ceilings, 10 feet. The front entrance is from a porch through double doors, to a hall which communicates with the parlor and kitchen, and contains the main stairs. The Parlor is square floored, with windows in two sides, and a marble shelf. The Kitchen is the largest apartment, and intended as the family living-room. It is convenient to a pantry,

closet, and rear entrance. The Pantry is thoroughly shelved, and has a small window. The Closet is formed in the space under the front stairs, and is shelved. The Rear Entrance is from a covered porch to the Entry, the latter is sufficiently large to contain the wash-tubs, and relieve the kitchen of much of the heavy work. The Bed-room is conveniently arranged, and may be entered from the parlor or kitchen. It has two windows, a closet, and a marble shelf....**Second Story** (fig. 4).—

Height in main house, 6 feet at the plates, following the rafters to the full height of 8 feet. The divisions embrace a hall, four sleeping-rooms, four closets, and a store-room and garret. The Chambers are commodious, have windows in two sides of each, and adjoin chimneys, giving opportunity for stoves when required. The Flues of the kitchen chimney are divided in the second story, admitting a window between, and are brought together over an arch above the window. A Tank shown in a closet fills half of its height; the balance of the space may be used as a closet. The Store-room might be used as a bed-room if required, and receive light from the rear window through a sash door....**Construction**.—The excavations are made 3½ feet deep. The foundations and chimneys are of hard bricks and good mortar (or stone may be used where cheaper). Frame of sawed timber, as indicated in the estimate below. Siding of wide "Novelty" pattern. Principal cornices of dressed pine, projecting 18 inches, and having in the gables verge boards of open panel-work. Roofs are set at an angle of 45°, and covered with pine shingles laid on 1½ by 2-inch lath. Floors of tongued and grooved spruce, 8 inches wide. Plastering, white finish upon two coats of brown mortar. Stairs of pine. The principal flight having a newel, rail, and ballusters of black-walnut. The principal windows have four-light sash hung to balance weights. Cellar sash two lights hung with butts to swing upwards. Doors are panelled and molded, and have hard-wood saddles. The plumbing is similar to that described and illustrated in the March *American Agriculturist*. Marble shelves, with appropriate stucco trusses, are set in the parlor and each chamber. Painting inside and out, two coats of best lead and oil....**Estimate**.—Cost of materials and labor.

**Agricultural Art and Science.**—Prof. W. H. Brewer, Yale College, in his address before the Am. Agr'l Association, spoke at some length upon the *Art of Agriculture* in distinction from the *Science of Agriculture*. The *Art* is old—almost as old as the race; it varies with the locality and the traditions of the times. The *Art* is local and change-

Fig. 4.—THE SECOND STORY.

able. On the other hand the *Science* is new—very young—and mostly confined to our own generation; it deals with principles that are fixed and general. When the art, that is, the practice of agriculture, is founded upon, and is the application of well founded principles—*Science*—then we may expect successful and progressive farming.

### American Merino Sheep.

Sheep-raising has formed an important part of the husbandry of most nations from the early historical times. Each country has had its peculiar breeds marked by characters, due in a great degree to the modifying influences of climate, and in part to a rude selection. In some cases these breeds have reached a high degree of development, while in other countries the flocks have shown no improvement for centuries. This country, young as it is, has made its contribution to the list of useful breeds in the *American Merino*.

of him that he is "hide bound;" the much esteemed wrinkles being large and sufficiently abundant to annoy the shearers, and to entirely meet the requirements of breeders, who regard this mark as important in an animal with which to improve the smooth-skinned native sheep.

The sheep industry in the United States is vast and important, and in the consideration of which there are two partially distinct, and at the same time, interlocking interests. Sheep were in early times grown almost solely for their wool, and with the annual shearing came the year's income; but in later times, and never so prominently as now,

tained that pays for itself in its wool of prime quality, and furnish a good quantity of mutton as a profit. Of such character are the crosses of the Merino with the Cotswold and the South-down. But with the great mass of American sheep on the western plains, wool is the important product, and here the cross must be with the Merino upon the "Native"—a race of sheep which has grown out of a variety of early importations to this country—an intercrossing of various breeds in which many of the good points have been lost. In this field the Merino has a great work to do to raise the yield of wool 1, 2, or more pounds per head, and give it a

A GROUP OF AMERICAN MERINO SHEEP.

Our climate and pastures have better satisfied the wants of this fine wool-bearing animal than those of its native country, and now the American Merino stands at the head of the fine-wool sheep of the world. This breed would seem to have reached that point in its development where it appears of but little use to try to further improve it. The first importations of Merino sheep into this country were those of Hon. Wm. Jarvis, the American Consul at Lisbon, in 1809 and 1810, who sent over nearly 4,000 head. From these Spanish sheep as a basis, and by means of careful crossing, breeding, and selecting from several distinct flocks, the present Merino has been produced, and is now so unlike other Merinos as to take rank as a distinct breed with the prefix "American." The accompanying engraving gives a group of these American Merino sheep. The ram, with his short, thick neck, straight and broad back, and general plumpness is an animal which unites a vigorous constitution with great beauty—as beauty is regarded in sheep—as seen in his fine head and pleasing outline. His wool is of medium length, thick and fine, and extending well down to the toes. It can not be said

the carcass is looked upon as an important item in sheep husbandry. Mutton as a cheap and acceptable meat has of late grown greatly in popularity, and mutton now stands as one of the two important factors in the successful raising of sheep. In view of the fact that the Merino is essentially a wool-producing breed, with a fleece of the finest and best quality, it is evident that the pure-blood Merino, though it may supply our manufactories with the material for the finest of woollen goods, on the other hand it can not satisfy the butcher. The sheep having to both feed and clothe its keeper; it is an important question: What is the best breed of sheep to do this? Evidently not the pure-blood Merino. Though the growing of pure-blooded Merinos has its place, and an important one, and the demand for their wool indicates the prosperity of manufacture of the finest goods, it is in the crossing of them with other breeds in which the flesh-producing qualities predominate, that a sheep best for both meat and wool is produced. A cross-bred is the one that in most localities is to pay. The Merino is slow of growth and small of carcass when mature; but when crossed with a rapid grower, one that matures early, is a high feeder, and lays on flesh rapidly, but not remarkable for its wool either in quantity or quality, a sheep is ob-

higher value. The opportunity for the increase of our sheep interest is almost without limit, so far as favorable conditions of vast plains and healthful climate is concerned, and with our present large importations of woollen goods it is certain that no raw wool would lack for a market. There are many places where sheep may go and thrive that cattle and other life-stock dare not tread; and it should be the ambition of sheep-raisers to fill all these places with sheep adapted to these conditions, in the production of which the pure-blood Merino must find its full share of work. The revival in the sheep interest that is now in progress is both healthy and permanent. The surplus of wool and woollen goods is exhausted, and the growing crop is in demand. The shipping of whole car loads of Merino rams to the flocks of the great West, with calls for more than the East can supply, is not in the nature of a "boom," but founded upon the demands of the time and the merits of the breed.

The rapid growth in our sheep industries is shown by the figures given by George Geddes in an article in the New York "Tribune" for February 26:

"In 1836 our production of wool was 42,000,000 pounds; in 1860 it had increased to 60,000,000. In 1867, the annual production had risen to 147,000,000 pounds, and in 1877 to 208,000,000, that is from

1860 to 1877, inclusive, the increase was at the rate of 246 per cent, while in the preceding twenty-four years, the increase was about 40 per cent.

"Since 1809 our improvement in the sheep that produce clothing (fine) wool has been very great. Then 9½ per cent of unwashed wool to the live weight of the animal was the standard; in 1864 the best recorded yield was 21 per cent, and the heaviest fleece 27 pounds. Three rams bred since 1873 in Vermont have yielded fleeces averaging 27.3 per cent of unwashed wool, while the average weight of the fleeces of the rams was 34½ pounds.

"Wool yielded by cross-bred Merino and mutton sheep is held by the manufacturer to be of great value, producing a combing wool that gives softness and cloth-like character to our fabrics not found in those abroad, as admitted by the best London and Paris tailors. We are now raising good mutton and supplying a rapidly increasing market. In 1839, on the great market day before Christmas, 400 sheep fully stocked the market at Brighton, near Boston, Mass. Last year 272,000 sheep and lambs were slaughtered at the Brighton Abattoir, 20,000 of them coming from Kentucky.

"Capital employed by manufacturers is nearly \$300,000,000 giving work to nearly 200,000 persons.

"The importation of wool in the form of manufactured goods is rapidly falling off. In 1860 our importation amounted to \$37,973,190. In 1878, our population having increased not less than 12,000,000, we imported only \$25,230,154. In certain classes this falling off of importations is very marked. In carpets the importation in 1878 was not one-fourteenth the value of the importations of 1872. Dress goods, in which the foreigners still lead our manufacturers in the estimation of certain wealthy consumers, are no longer imported as extensively as formerly, their value having fallen in 1878 to \$12,000,000 from \$20,090,000 in 1872.

"The wonderful progress made, to the great benefit of the whole Nation, is before us, and our flock owners having surmounted the difficulties of changing the flocks of the East into producers of long wool and mutton, and transferring the production of fine wool to the West and Southwest, we look forward to profitable production of wool, combined with mutton, in New-England, as has long been the case in Old England, and abundant rewards to the owners of flocks of fine-wooled sheep in their new homes. In view of the foregoing facts, may not the wool-growers and the wool-manufacturers justly claim that they have largely contributed to the balance of trade in our favor, and to the ability of the Nation to resume specie payment?" The above facts and figures are worthy of study.

### Among the Farmers.—No. 51.

BY ONE OF THEM.

#### Sam Stone's Horse-Shoe.

There is one brawny wielder of the hammer and draw-knife who studies his trade and loves it, tempering horse-shoeing with humanity. I will tell about him by and by—but first, do all my readers know what a delicate and beautiful *box* a horse's hoof is? The *box*, figure 1, is in external form a segment of the base of a cone, tough and elastic. The sole of the foot is attached to it in such a way that it has a free up and down play with every step—bringing the frog down to a bearing upon the ground. This substance, which is called a *frog*, and indeed the sole and frog together, are not intended to sustain the whole weight of the horse, as is evident from the fact that every horse winces when forced to tread with his whole weight upon them, as when he steps upon or picks up a stone. Figure 2 shows a longitudinal cross-section of a horse's foot, and the relative position of the frog, sole, laminae and shell. His weight is chiefly borne by the horny shell—and one who has not studied the horse's hoof will be surprised to find that the weight of the horse is really *suspended* from the inner walls of the hoof by delicate curtains, or leaves of horn, called the *laminae*. They form the entire inner surface of the hoof walls, and are enclosed, each one by itself, in a vascular membrane, and so closely connected with the half moon-shaped bone, called the *os pedis*, which is the sup-

porting bone of the column of the leg, that at times the laminae of one foot support almost the entire weight of the horse, for the weight is borne very slightly upon the sole in most cases. There are about 500 laminae (so the books say,) in each foot, in all four feet, 2,000, of course, so that the weight which each one of these many thin laminae has to bear is only a pound or so at the most.

Fig. 1.—HORSE'S FOOT.

stance of sound hoof-walls, and to describe a shoe which I have had in constant use for some months.

We all know that in icy weather horses must have sharp calks, and this is especially true in cities where the pavements are much more slippery in winter than in summer. Calks in horses' shoes are very soon worn down flat, or pounded smooth, so that the shoe has to be taken off, new calks put on, or the old ones sharpened, and the shoe nailed again upon the foot. The hoof-walls, which we have seen support nearly the whole weight of the body, are thus weakened or destroyed by the nail-holes, (fig. 1, *a*), and the horse sometimes rendered useless until a new horn has grown out upon the foot. A more frequent result is that the shoes tear off or are "thrown" or "cast" off, and the animal is not unfrequently strained by slipping, or his hoof further injured before the horse can be re-shod.

The shoe I have been using avoids all this, in no new way in one particular—but quite new in another.

Fig. 2.—CROSS-SECTION OF HORSE'S FOOT.

There are calks provided which screw into the shoe, there being two toe-calks and one in each heel, making four to each shoe, fig. 3. This is an ancient device, and one which has worked very well for 100 years for aught that I know. These screw calks, of soft iron, wear down smooth in half a day's service, and then slip badly. Steel ones have been used, and these last longer, but do not hold so well upon pavements. The practice prevailed among some of changing one calk every day or two, so that the horse may always depend upon one to hold from slipping on each foot.

Mr. Stone's improvement consists in making an iron calk with a small steel core, fig. 4. In use, the iron, being soft, wears away, and the steel maintains the point in good form a long time. When they wear they are of course replaced, one at a time preferably, though it makes little difference, as all remain sharp. My horse, which has worn this shoe, has been shod but once this winter, but his calks have been renewed several times. My attention was directed to these shoes by Mr. J. B. Olcott, the Agricultural Oracle of the "Connecticut Courant," who has used them for eight winters. He writes very enthusiastically about them, and I must say I do not think him at all extravagant.

Fig. 3.—THE SHOE.

#### Right Angles.

In laying out a new line of fence, staking out for a foundation, and in doing a thousand and one things, we have to lay off right angles, or it would be better if we would, rather than to guess at them. Most of us remember the "asses' bridge" of the geometers—that "the square of the hypothenuse of a right-angle triangle is equal to the sum

of the squares of the other two sides." If one has a ten-foot pole—or a tape line, or even no measure at all but a bit of pack thread, he can lay off his right angle with great accuracy. The numbers 3, 4, 5, give the sides of the triangle. See figure 5. *A, B*, is the base line. The point *C* is fixed. Measure off *three*

Fig. 4.—SECTION OF CALK.

anythings (feet, yards, five-foot or ten-foot lengths), and drive a stake at *D*, then measure off *four* lengths from *C* and *five* lengths from *D*, and thus determine the point *E*, which will be in a line at right angles to the line *A, B*, at *C*. This is absolutely a right angle, as may be proved practically

Fig. 5.—PLAN FOR GETTING A RIGHT ANGLE.

by putting another point on the line *A, B*, the other side of *C*, and finding that the distance to *E* will be the same as from the first *D* to *E*.—Three times three is nine; four times four is sixteen; nine and sixteen is twenty-five—which is also five times five. On the same principle one can nail three furring strips together for a big "square," to get levels or to secure perpendicularity in posts, stanchions or erections of any kind—or to mark out right angles upon the ground. One or both of the sides forming the right angle must be arranged for a plummet or "plumb bob" as the workmen call it, as shown in figure 6.

6.—TRIANGLE FOR PLUMBING.

#### Cooling and Ventilation of Milk and Cream.

While it is quite true that the utmost care as to the food which cows eat, and in the matter of stables and milking does not suffice to remove entirely what is known as the "cowey odor," it is a fact that a great part of it may thus be avoided, and that proper rapid cooling and ventilation of milk while cooling is of the greatest service in improving the flavor, and securing longer keeping qualities in the milk, the cream and the butter. A ventilated can or pail cover for milk placed in pools or in springs for cooling was introduced somewhat last year. This consisted of a tolerably close fitting cover having a large tube, four or five inches high in the top. This tube is divided perpendicularly by a *septum* or partition making virtually two tubes. One of these is closed at the top, but has a large opening in the side to the outer air, which is covered with wire gauze. The opening of the other half of the tube at the top is covered also with gauze (see fig. 7). So long as the

Fig. 7.

milk is warmer than the surrounding air, the air blows in, circulates over the milk and passes off, following the direction indicated by the arrows.

This top is useful for milk set in pools or springs to cool, or for milk set for cream to rise. The milk being perfectly protected from insects, animals and dust, or foreign matter of any kind, while a free circulation of air is passing over its cooling surface so long as the milk is warm at all.

#### A Milk Stirrer.

Mr. J. C. Long, of Orange, added for his own use an improvement to this useful invention, rendering it a perfect and rapid means of cooling milk.

This is a *Stirrer*, which is simply a disc of tin from which a long stiff wire rises and passes through the ventilator in a small tube made for the purpose. By means of this wire the tin disc, which is 4 to 6 inches in diameter, is moved up and down through about three inches space in the bottom of the can or cooler—the down strokes being quick and strong. Three strokes are sufficient to change all the milk in the can, causing that at the bottom, and coldest, to be stirred through all the rest.

If more milk is to be added the top is slid off half way and is held by the stirrer-wire. Figure 8 shows a 40-quart can of the modern kind, supposed to be standing in a spring or tub of ice water.

#### A Cream Can.

Cream, as taken from the pans, coolers, or other milk-setting vessels, always contains a notable

Fig. 8.—A 40-QUART CAN.

quantity of milk which separates from it in the course of a few hours. If cream is sold as such, it should be solid cream, of course. There are two ways for getting solid cream—dipping it out of the cream jars or cans, or drawing the milk from under it. The latter mode is preferable.

I have in use a cream can which holds six or seven gallons (see fig. 9). It is provided with the ventilating cover and stirrer just described, and has a window at the bottom to show how much milk separates. At the bottom there is also a spout, closed by a cork. Whenever cream is added, the whole mass, new cream, old cream, and milk, are stirred together, by a few dashes of the stirrer. This cream holder may be kept cool by being placed in water, or by having lumps of ice laid upon the top, and thus the cream freed from

Fig. 9.—A CREAM CAN.

milk is ventilated and kept sweet at the same time. When cream is to be ripened for churning, it

Fig. 10.—CREAM WARMER.

should be kept at a temperature of 60 to 63 degrees until it turns slightly sour. This cream-holder, when used for this purpose, may be set in lukewarm water, in a warm room, or upon hot water or steam pipes, where such means of heating are used. Where either of these can be had and controlled, it would be very convenient to have warmers made for the purpose, to be placed under the cans (see fig. 10). This warmer being connected by a rubber tube to the hot water tank, or pipe, would be kept at any desirable temperature by allowing more or less water to flow through it.

The best way of ascertaining the temperature of milk or cream, is by means of a floating thermometer. One advantage which the *Stirrer* described offers, is that the milk may be thoroughly stirred while the thermometer floats in it without its receiving any injury; further the test is more accurate.

#### Gilt-Edged Butter.

There is no doubt that much of the present improvement in the quality of butter is due to recent methods of setting milk, churning the cream, and preparing the butter for packing; and these are a natural outgrowth of the factory or creamery system of dairying. It is a notable fact that the highest-priced butter on the general markets is that from creameries, in which every new and improved device for aiding in butter making is tested and used if found worthy. The dairy system gave way to that of the creamery, because no single dairy could afford to procure the needed machinery and skill for producing the finest butter. But now a small dairy can find it profitable to use the most modern appliances because these are adapted for all uses, and to furnish the dairy of one cow or the factory of 1000. For setting the milk there are the deep-can and the shallow-pan creameries, and it is an undecided question among dairymen which of these two systems is the better. Premium butter has been made on each system, and the question is really nothing more than one of convenience and inclination, not to say prejudice. The Cooley System of deep setting, with submerged cans, is an excellent one for those who prefer the deep cans. A new and shallow-pan creamery, which cannot fail to please neat and ambitious dairymen is the Ferguson Bureau Creamery. This is so arranged as to provide every facility for cooling the milk in the summer or warming it in the winter, for preserving the milk free from dust, and for aerating and exposing it to the light. It is provided with glazed doors, and with ventilating openings which are protected by gauze covers, and is not only very convenient for its purposes, but a neat, if not handsome, piece of furniture for the house, dairy, or butter factory. The pans are square, of different sizes, and about 6 inches deep. An arrangement is made for drawing off the milk from the bottom of each pan. But it is upon the churning that the character of the butter chiefly depends. Of the great variety of churns there are but few which give general satisfaction, and still fewer with which butter can be completely made and prepared for packing in the churn. In figure 1 we give an engraving of butter made by the new method of churning without dashers. It will be noticed that this consists of small grains of the size of sago grains, loosely aggregated together. The butter from which this drawing was made was churned in the Rectangular churn (shown in figure 2.) As this is revolved by two opposite angles, a very complete agitation of the cream is secured, and 8 to 12 minutes is sufficient to bring the butter, in the condition shown in the engraving. The butter lies so loosely in the churn that the buttermilk can be drawn off from an opening at one of the angles, and cold water being poured in; by revolving the churn a few times, the butter is thoroughly washed, and freed from the buttermilk. A

method of washing butter with cold brine, we believe, when in this condition, has been patented; of the justice of the claim to a patent on this so-called

Fig. 1.—FINE GRANULAR BUTTER.

improvement we have nothing now to say, excepting that the method is by no means new; but to avoid interference with a patent, just or unjust, another plan may be pursued. After the butter has been washed, salt may be sprinkled over it, and a few more turns of the churn thoroughly mixes it. A rest of a few hours for the butter to drain may be given, and it is then ready for packing, more salt being added if necessary. Some experience with this churn in the writer's dairy has been very satisfactory, and its simplicity is such that any person, not an expert, can hardly fail to make the best quality of butter in it, after the first attempt. The advantage of using the best dairy appliances is obvious. Price depends upon quality, and quality depends upon the use of the most effective implements. There is no reason why all dairy butter should not be equal to the best product of the creamery, all that is needed, good cows being secured, is to use the same means and methods of manufacture, and the best dairy appliances may be

Fig. 2.—THE RECTANGULAR CHURN.

procured at such a reasonable expense, that the extra value of the butter from a small dairy of only five cows will pay for an outfit of a creamery, and a churn of the best kind in a single season.

**A Jersey Cow's Record.**—It is not rare to find a heavy milker among Jersey cows, yet the average is by no means extraordinary. Possibly a true record of a whole herd of Jerseys as to weight of milk would fall below that of a herd of natives even, and greatly below that of an Ayrshire herd. A notable record of an English Jersey cow, however, is worth recording. The cow is "Luna," owned by Mr. Simpson. In 1876 she gave 8,985 lbs.; in 1877, 8,202 lbs.; in 1878, 8,368 lbs.; an average of 8,518 lbs. per year, or equal to a daily average of more than 23 lbs. or 11 quarts. One of the most conspicuous characteristics of a Jersey cow, is her persistence in milking, and although she may not give so great a yield, yet by hanging on during 300, or 330 days, she makes up by perseverance, what others do by more copious, but less continuous milking. If there were only more Jerseys like this one!

### Fence-Post Driver.

A fence-post driver on the plan of a pile-driver is shown in figure 1. This is made to fit upon a wagon body, resting on the sill *a*, and being held down by the bolt *b*, which is provided with a thumb screw. The upright post, *c*, one-half only of which is shown, so that the peculiar arrangement can be seen,

Fig. 1.—PLAN OF FENCE-POST DRIVER.

is 15 feet long, and 12 feet above the sill, 3 feet being below it. On the lower part a pair of guides are provided which clasp the post loosely, and cause it to be driven in the right direction. The driver (*e*) is of the usual kind, provided with flanges which run in grooves in the upright posts that serve as guides. The driver is lifted by a forked catch, through which the hoisting rope passes, and a round button fastened on the rope at proper intervals, engages in the catch and so raises the driver. When the driver is lifted to the top of the post, the button strikes a cam (*f*), which is made with a groove through it to admit a rope, and the button, not being able to pass through the groove, is drawn by the edge of the cam out of the forked catch, so

Fig. 2.

as to liberate it and let the driver fall on to the head of the post. The rope is an endless one, passes over rollers (*g*); and having one turn around the winch (*h*). As the winch is turned the rope is drawn under and over the rollers, the button passing over these, and as the driver falls, a button is ready to take it up again. So that the action is continuously forward, and no rope has to be lowered to pick up the driver. This saves much time and an extra hand, one man alone being able to do all the work if necessary. The posts are held by the guides as shown in figure 2. The head of the post is not driven any lower than a few inches above the guide. The driver should be of cast iron, and, to be most efficient, weigh not less than 50 pounds.

**Tape Worms in Lambs.**—Tape worms frequently infest sheep and lambs, but injure only the lambs, as these are not robust enough to resist the irritation caused in the bowels. When the lambs are troubled with diarrhoea, and scales, and flat ribbon like fragments are found in the dung, tape worms are present. Then 2 ounces of Pumpkin-seed, mashed, or pounded to a paste; or the same quantity of powdered root of Male Fern; or 2 ounces of Raw Linseed Oil, with half an ounce of Spirits of Turpentine, may be given, and repeated at the end of six days. Two ounces of the oil should be given six hours after the administration of the Pumpkin-seed, or Fern-root. Sometimes a large quantity of segments of the worm may stop the bowels, and cause constipation instead of diarrhoea. In this case, the belly will be found tense, and filled as with wind or gas, and in each case

an injection of the oil may be given, followed immediately with another of blood-warm water.

### Hints and Helps For Farmers.

**A CORN MARKER.**—An Indiana farmer sends sketches of a very useful corn marker, which is adapted for uneven, as well as for smooth ground. The implement is shown in figure 1. There are 4 markers connected by cross-bars, and strengthened with braces. The cross-bars are 2 by 3 inches, fitted in notches in the runners, and are hinged so that the runners will adapt themselves to uneven ground, as shown in figure 2. The runner shown in figure 3, is 3 feet long, and 14 inches wide. The hinges are made of rods and eye-bolts, such as are used for harrows. When moving to or from a field, the outer runners may be turned up, as shown in figure 4.

Fig. 3.

**To SLING A BARREL.**—It is often desirable to hoist a barrel to a loft or elsewhere. In this case one should know how to sling it. This may be done as shown in the illustration. A rope is passed around the barrel, and a half-twist is made in it. The end is then carried under the bottom, and brought up on the other side, where it is passed around and brought back, and a half hitch taken

Fig. 5.—A SAFETY KNOT.

on the side opposite to the first one. The ends of the rope are then tied, figure 7, thus making a sling by means of which the barrel is easily hoisted.

**SAFETY KNOT.**—Mr. L. Osius, Washtenaw Co., Mich., sends sketches of a Safety Knot, of which

Fig. 6.—SINGLE BOWLINE KNOT.

we give engravings. Figure 5 shows how the knot is made; *A*, the end of the rope, and *B*, the continuing part. The knot is useful and handy for many purposes, as binding loads of hay, etc.; in fact, for all work when a rope with a safe knot is needed.

**ANOTHER KNOT.**—Our old friend, Jas. B. Olcott, in sending a holiday greeting, after his usual manner of combining the "useful with the agreeable," sends a note about a knot, illustrating it by the knot itself. Though we illustrated this knot some years ago, we give it again on a larger scale, as it allows us to show an important improvement in the use of wire for whipping the rope. He writes: "I have been thinking of sending you a Single Bowline this long time. It is one of the most useful knots on the farm. I think it indispensable for tethering calves and

Fig. 7.

cattle, because it will never untie when once properly drawn in place, and no matter how tight, or stiff, or wet it gets in use, it may be untied

with ease and in a moment. This is the knot we see sailors using when they throw a line to the

Fig. 1.—CORN-MARKER.

wharf with a hawser, knotted at the end, to make a vessel fast by. It makes no odds how taut she hauls the cable, the big knot that holds her will loosen with a turn of the wrist. The wire-whipping at the ends of the bit of cord speaks for itself. That whipping will outwear any rope. I bend the wire around the end of a rope by successive bites or pinches in an iron vise, coaxing the ends of the wire into place, now and then, with a light hammer." This is much better than using thread.

Fig. 2.—A RUNNER.

Fig. 4.

### A Barn for Sheep.

Several ask for a plan of a sheep barn, in which cut feed can be used. As a rule, sheep do better on long feed than on that which is cut, or prepared in any way. They masticate their food thoroughly, and in so doing, it is well mixed with saliva, which acts as a solvent of the food, and without which digestion is not perfect. Cut or cooked food is more easily swallowed than long hay, coarse straw, or unground grain, and sheep do not thrive so well upon it. There is some economy in using cut food, and this may in some cases perhaps make up for defects in other ways. But the arrangement of the barn does not depend entirely on the system of feeding; the interior arrangements may be so made, as to be applicable to any method of feeding, and a building of this kind is here described. The ratio of available space in a building, as compared with the length of the wall, depends upon the form; a square building, with 96 feet of wall, will be 24 feet in diameter, and contain 576 square feet in area. A circular building with 96 feet of wall, will be 30½ feet in diameter, and have an area of 732 square feet; an octagonal building with 96

Fig. 1.—PLAN OF OCTAGONAL SHEEP BARN.

feet of wall, will have a diameter of 29 feet, and an area of 696 feet, and a building of this shape, will be built much more conveniently and cheaply, than a round building. For sheep, the octagonal form is especially well adapted, because the largest space is needed, and no fastenings or stalls are required. The inner arrangement for feeding, too, may be

made with the greatest convenience in a barn of this kind. At figure 1 is given a plan of an octagon sheep barn, supposed to be 36 feet in diameter, and intended for a flock of 150, to 200 sheep. A range of feed racks, made as shown at figure 2, runs

Fig. 2.—ARRANGEMENT OF FEED RACKS.

around the barn, and another 9 feet from it; the latter is double, and is fed from both sides. Feed spouts are dropped from the floor above at convenient intervals, to carry the cut chaff into the feeding troughs. The most economical power for cutting the feed, would be a wind-mill, placed over the center of the barn, and a well might be dug in the center of the building, from which water could be forced into troughs in a yard made around it. The feed trough is made as shown at figure 3, consisting of a box for the feed with a sloping board in

Fig. 3.—CONSTRUCTION OF FEED RACK.

front, coming down to within 4 inches of the bottom, to prevent the sheep from wasting the fodder. Sloping stakes should be fixed about 2 or 3 feet apart in front of the troughs, to prevent the sheep from crowding each other away from their feed. A push rake, (fig. 4), would be found useful for putting the chaff into the spouts. It would not be advisable to wet the feed for the sheep, the labor would not be repaid by any advantage that might be gained. Any grain which may be given to the sheep, might be fed in the troughs once each day

### The Sewage Waste of the Family.

We are making some progress, both on the farm and in the village, in utilizing the contents of the sink-drain, and the water-closet, or the earth-closet. But still there is great room for improvement. We consume in our families abundance of animal food, furnishing all the materials out of which plants are made. These fertilizing matters are nearly all wasted, unless there is some contrivance to incorporate them with the soil. If properly saved, the wastes of the family would fertilize the half-acre garden adjoining the dwelling, and make it produce

Fig. 4.—A PUSH-RAKE.

maximum crops of fruits and vegetables for the supply of the table. We have tried the two most common methods, that of composting fecal mat-

ters, and that of turning them into a cistern for the manufacture of liquid manure. While both are good, and each has its advantage, we prefer the application of these wastes in the form of liquid manure. There is not much choice in either case as to the labor to be expended in conveying fertilizers to the soil. The use of the liquid manure involves a little more expense in the fixtures. For this purpose a cistern is needed of sufficient capacity to hold all the water used in the family for six or eight weeks. The privy vault enlarged and cemented will answer a good purpose. A large earthen or iron pipe four or more inches in diameter, should conduct the sink and laundry water into this cistern. This liquid manure can be used to advantage at all seasons of the year. For the seven months or more it is available for direct application to growing vegetables and fruits in the garden, and for the winter season it can be pumped on to the compost heap where all the vegetable wastes of the garden, and leaves, and muck, are fermenting for next season's use. This liquid not only furnishes plant food, but supplements the rain-fall which is oftentimes quite deficient for maximum crops. So great is the satisfaction of seeing luxuriant vegetation in the garden, and of eating well-grown fruit and vegetables, that we should use liquid manure even if it was more expensive. CONNECTICUT.

### Stable Windows.

Many horses are made partly or completely blind by want of windows in the stable, or by windows improperly placed, or not correctly made. If the light comes from one side only, the eye furthest from the light receives less of

Fig. 1.—SLIDING STABLE WINDOW.

the sun's rays; if it comes from behind, it is almost as injurious to the sight; if there is no light, the sudden transition from darkness to bright sunshine, more especially in the winter when snow is on the ground, is painful and injurious. A direct face-light is preferable, but a diffused light is better than any other. It is rarely possible to have windows on every side of a stable, and therefore

Fig. 2.

Fig. 3.

may be fitted below the window, for use in bright weather, as shown at figure 2. This shade is hinged below the window, and may be made to rest on brackets, and form a shelf if desired, or may fall down against the wall. It may be raised by a cord or a short brace from the wall. It should be painted white, so as to reflect and diffuse the light as much as possible. An excellent kind of window is a swinging sash (fig. 3), which, being made to swing out at the top, and in at the bottom, provides at the same time a good means of ventilation. The air will escape at the top, and pass in at the bottom as shown by the arrows. Stable windows, upon which direct sun-light falls, should be shaded by spatter-work, done by spraying lime-wash on the glass, from a paint brush over a round stick. This covers the glass, and while it is translucent, it is not transparent, and softens and diffuses the light.

### Pure Cistern Water.

There is frequently much difficulty arising from impure cistern water. Constant complaints are made of it, and inquiries often come to us to know how to purify the water or cleanse the cistern. The difficulty arises from the admission of impurities into the cistern, not that there is anything wrong with the cisterns or with the method of keeping

PURIFIER FOR CISTERN WATER.

the water. The impurities are carried in with the first water of a shower that falls, washing the roof of all the various accumulations that gather upon it and in the gutters during the dry weather between the rains. Numerous insects and leaves, a large quantity of dust and various organic matters, such as the droppings of birds, pollen of trees, spores of fungi, etc., are thus carried into the cistern, where they decompose, ferment, and foul the water. This is not nearly so easy to cure as to avoid. It may be prevented by some arrangement by which the first water is turned from the cistern into the overflow, with the gathered impurities.

Such an arrangement is shown in the accompanying illustration. The leader from the roof is connected with a pipe into the outlet, as shown, and a valve is made to shut off the water from the cistern (at a). The valve is connected with a lever, weighted at one end to keep it closed, and at the other end is a receptacle for water which runs in a small stream from the offset of the leader pipe. When the rain falls, the water flows off into the outlet, a small portion falling into the receptacle. When this is full it overbalances the weight, and drops, when the valve is moved, so as to close the waste-pipe and turn the water into the cistern.

### Farm Ladders.

The accompanying engravings of farm ladders, (for which we are indebted to the "London Agricultural Gazette"), show very clearly their character and uses. These are made in sections, connected in such a manner, as to be rigid or pivoted, as may be required for different purposes. The ladders may be joined so as to form an independent step-ladder, for use in the orchard or in build-

HANDY FARM LADDERS.

ings, or as a long ladder, that may be turned over the peak of a roof for thatching or shingling. By using a third section placed upon a stack, it may be used for building up, or for finishing off the top.

## Saws and How to Use Them.

The idea of a saw was probably first suggested to mankind by a jagged edged knife. Some insects are provided with very perfect saws, such as, for instance, the well known seventeen-year locusts, the saw flies, and the wood wasps. Insects were, in fact, the first sawyers, and sawed for their existence ages before a human being thought of a saw. A Grecian story relates that an uncle, Dædalus, and his nephew, Talus, invented the saw almost simultaneously by first discovering that the jaw bone of a snake could be used for cutting wood, and improved upon the idea by notching an iron plate. As in modern times, each one of these

Fig. 1.—A THEBAN SAW.

inventors claimed priority, and there being no patent office to appeal to, the uncle decided the dispute in the old fashion way by killing his nephew, which was a summary and effective manner of settling what a patent lawyer would now call an "interference." Ovid, who is known for his

Fig. 2.—A JAPANESE SAW.

doubtful way of giving facts, states that one Perdix, another nephew of Dædalus, made the discovery by using the back-bone of a fish, and was changed to a Partridge by some jealous rival; it is not stated whether his rival plucked him clean, as is done

Fig. 3.—A KEY-HOLE SAW.

now sometimes. Then, as now, we see that the inventive faculty seemed to run in families. Saws were made in what is known as the stone age, when

Fig. 4.—KEY-HOLE SAW NO. 2.

only stone tools were in use, by cementing sharp flakes of flint into wooden handles. Saws of a very hard and glassy volcanic stone, known as Obsidian, have been found in New Jersey under several feet of gravel. Saws of the bronze age have been found in Germany. After bronze, iron came into use, and saws (very much like ours of the present day) were employed by the Egyptians. A saw found in the ruins of Thebes, and now in the British Museum, is represented at figure 1, and some old writers of nearly 2,000 years ago are supposed to have known of circular saws. The saw in figure 1 is fastened into the handle by means of a tang, as our knife blades are. Saws are frequently mentioned in Scripture, and

Fig. 5.

stone, even, was cut with saws for Solomon's temple. The fact is, that every form of modern saw which is supposed to be of the very latest invention, has been known for many ages; circular saws were in use in 1777, and even the supposed to be recent band saw was patented in England in 1808. Besides, some very old saws are much better, and made on more correct principles than our modern ones. For instance, who has not been annoyed when using a key-hole saw to find the blade catch and bend nearly double, and sometimes snap off as it is pushed through the wood. But the Japanese and Chinese, and other Asiatics, have used saws of this kind for centuries that are free from this objection. At figure 2 is shown a Japanese saw that was used by a Japanese

Fig. 6.

mechanic at the Centennial Exhibition. The teeth are seen to be inclined in a direction contrary to our usual method, and a key-hole saw thus made (fig. 3) could not possibly bend or break while in use, as that shown at figure 4 would certainly do in the hands of one that was not an expert in the use of saws. With this exception, our saws are now more effective than saws ever were, because the principle upon which the teeth work is well understood. The teeth are used first to cut, then to open an easy channel in which to work, and lastly, to remove the chips or sawdust. The form of the teeth and the "set," or bend given to them, enable them to perform these operations properly. The best form, of course, has been discovered by gradual experience. If a novice attempts to cut a board across the grain with a rip-saw, he will find out that the shape of the teeth has much to do with the work, and that for cross-cutting and cutting along the board in the direction of the fibres, differently shaped teeth are required. A cross-cut saw cuts across the fibres of the wood, and sharp-edged teeth, filed to sharp points, so as to tear the fibres apart, are required. These teeth are triangular, and are most frequently cut at an angle of 60 degrees (fig. 5), and sometimes at an angle of 50 degrees (fig. 6). For greater ease in sharpening, the form of the tooth has been changed in mill saws, as shown at figure 7, and this, by degrees, was improved to the "briar-tooth," figure 8, which is well adapted for the scraping or paring action used in rip-sawing timber. In ripping, a sharp chisel-like cut is made along the fibres, and the piece pared off is wedged out of its place by the teeth, the fibres having little adherence together as they lay side by side. This may be readily seen by the ease with which a board may be split lengthwise. This action is facilitated by the set of the teeth (fig. 9), each alternate tooth being bent outwards, so that the cut is wider than the blade of the saw. Formerly the teeth were bent over in sets of several at one side (fig. 9) alternately, but now each alternate tooth is set. Some sawyers upset or swage the teeth (fig. 10), which has the same effect as setting, but is better, because each tooth has two cutting corners. The teeth of a

Fig. 7.

Fig. 8.

cross-cut saw divide the fibres across, and reduce them to dust, the edges being sharp, to produce a clean cut (fig. 11). This is the M form of tooth, which was first described in 1846 in Germany, and it is, in fact, a doubled ordinary saw tooth, cutting both ways, and is therefore very rapid in its action. The teeth are usually set by bending the whole doubled tooth (fig. 12), but sometimes each half-tooth is bent alternately. This form of saw cuts in a remarkably easy manner. Perhaps the most useful innovation in sawing, is the use of the band saw, in which no back stroke is made, but a continuous down-stroke of a thin saw-plate, which runs over two large pulleys. This is an improvement on the circular saw, which has also a continuous motion, as the band is always tight and rigid, and does

Fig. 9.—TEETH SETTING.

Fig. 10.—SWAGED TEETH.

which was first described in 1846 in Germany, and it is, in fact, a doubled ordinary saw tooth, cutting both ways, and is therefore very rapid in its action. The teeth are usually set by bending the whole doubled tooth (fig. 12), but sometimes each half-tooth is bent alternately. This form of saw cuts in a remarkably easy manner. Perhaps the most useful innovation in sawing, is the use of the band saw, in which no back stroke is made, but a continuous down-stroke of a thin saw-plate, which runs over two large pulleys. This is an improvement on the circular saw, which has also a continuous motion, as the band is always tight and rigid, and does

Fig. 11.—THE M FORM OF TEETH.

not spring as a circular saw sometimes will (into a dish form,) by the heating and expansion of the outer portion of the disc. As saws are wasted by filing, the space between the teeth is removed by "gumming," which is cutting away the metal, or punching it out. To render this operation easier, some saws are made with holes in the lines of the "gullets" (fig. 13); rounded gullets are stronger than acute angled ones, and do not crack as easily as the latter do (fig. 14), and the holed saws are convenient, not only on this account, but because a crack that may start, will not go beyond the first hole. For the purpose of clearing the saw-dust, a few teeth are sometimes left without set, and filed shorter than the others, but this is not necessary if ample room is left in the gullet to carry out the sawdust. American saws were formerly considered inferior to the English, but by care and skill in the manufacture, they are now superior to the English, and are largely exported to England. An American mechanic now insists upon having an American saw.

not spring as a circular saw sometimes will (into a dish form,) by the heating and expansion of the outer portion of the disc. As saws are wasted by filing, the space between the teeth is removed by "gumming," which is cutting away the metal, or punching it out. To render this operation easier, some saws are made with holes in the lines of the "gullets" (fig. 13); rounded gullets are stronger than acute angled ones, and do not crack as easily as the latter do (fig. 14), and the holed saws are convenient, not only on this account, but because a crack that may start, will not go beyond the first hole. ## Shell Marl, Oyster Lime, and Swamp Muck.

The recent numbers of the Weekly Bulletin of the Connecticut Agricultural Experiment Station, under the able directorship of Professor S. W.

Fig. 13.—HOLES IN THE "GULETS."

Johnson, have contained information of value to the general farmer. In the number for February 7th is an analysis of a Shell Marl which is shown to consist of 40 per cent of Carbonate of Lime and about 2 per cent of Carbonate of Magnesia, the remaining being mostly sand and moisture.

"There can be no doubt that its employment, in liberal quantities, viz: one or more tons per acre, especially upon grass lands, would often be attended with decided and long-continued benefit, but, in most cases, its action upon grain crops would not appear at once in so decided a manner as is very commonly the case with good superphosphates or guanos.

"The fertilizing effects of this Shell Marl, as well as its commercial value, may be safely measured by the percentage of lime which it contains."

It is proposed to put this marl on the market as a fertilizer at \$15 per ton, a price that is far more than the material is worth.

The analyses of Oyster-Shell Lime, of which three are given in the same Bulletin, show that the principal constituents are Carbonate of Lime and Hydrate of Lime, with small quantities of Potash, Soda, Magnesia, and Phosphoric Acid.

"When applied to land, oyster-shell lime may act as fertilizer strictly speaking, or as an amendment. Commonly, both kinds of action are exerted, and the distinction between fertilizer and amendment is not generally recognized in practice, although very important in considering the effects of this substance. Lime is used as an amendment on heavy clay soils, 2 to 3 or more tons being sometimes applied per acre. On loams or light lands

Fig. 14.—SHOWING A CRACK.

1,000 pounds, or 20 bushels of Oyster-Shell Lime, applied once in two or three years, is a usual application, equivalent to the addition of 300 to

500 pounds to the acre, annually. It is evident that the small quantities of potash, magnesia, and phosphoric acid contained in such doses of oyster-shell lime can have no sensible effect upon crops.

Fig. 1.—A HINGED GUARD.

It is the lime alone, therefore, to which any benefit must be ascribed. A consideration of the modes of action of hydrate of lime, when applied as a fertilizer, will make evident that it is one of the most valuable aids to the farmer and deserves more attention from land owners than it has received.

"Our cultivated crops contain on the average as much lime as potash. The necessity for the application of potash salts is fully recognized, but probably the lack of lime is as common a cause of unfruitfulness; for while potash seldom wastes from the soil to any serious extent, and is found in

Fig. 2.—WOODEN FIXED GUARD.

spring, well, and river waters, in extremely small quantities, lime freely dissolves in water and rapidly wastes from the soil, so that other things being equal, there is more need for its restoration."

The three samples of Peat or Swamp Muck, the analyses of which are given in a later Bulletin, contain 2 to 3 per cent of Nitrogen, which, when the muck is acted upon by an alkali, like lime, becomes available plant food.

"There can be no doubt that the application of this swamp muck, especially to poor, light soils, would be very serviceable. Evidently, however, the large proportion of water which the fresh muck contains makes it a nice point to decide how much can be spent upon its handling without consuming the profit of its application. The proper mode of using swamp muck is to throw it out where it will drain and dry for some months, during frosty weather, and to employ the weathered muck as an absorbent in the stables or barn yard, or to com-

Fig. 3.—GUARD FOR GRAIN-BOX.

post it with lime, fish, or any other animal matters yielding ammonia by their decomposition."

### Guards for Feed Troughs.

To prevent the feed or hay from being thrown out of the mangers or feed-boxes, a practice which some horses indulge in very freely; it is customary to use guards, which may be either hinged so as to be raised up as shown at figure 1, or fixed across

the manger as at figure 2. The guard, like figure 1, may be made of strong wire, or light bar-iron, riveted together, or it may be merely a wooden frame. The guards shown in figure 2 are simply wooden cross-bars, so fixed by means of nails, that the horse or cow cannot throw out the feed with its nose. For feed-boxes the guard may be made by nailing pieces across the corners, as shown at figure 3, if the box is not large enough to allow them to be nailed lengthwise. Some such device as shown in the engravings, should be provided, whenever there is a disposition on the part of the animal to waste its feed. A few minutes in making a guard of some kind, will save many times its cost in the course of a few weeks.

### Poultry Farming.

There is no other branch of stock keeping that seems to be so popular or promise so favorably as poultry raising. The general idea is that the business consists of throwing out corn to a flock of hens with one hand and gathering eggs with the other. But while this may be true in some cases, it is very different in others. It is very interesting for a novice to watch an expert performing some intricate operation with the greatest ease and coolness and with perfect success, and he may think it is a very simple matter. It is the same in regard to poultry keeping; the expert poultry fancier meets with no difficulty and all goes on smoothly, but the novice is in trouble from the first; the eggs are few, the chicks die, vermin and disease destroy the flock, and the attempt ends in disaster. Probably the reason is, that too much has been attempted and failure has resulted as much from this as from want of attention. One may very easily keep 10 or 12 fowls with profit, who could not easily double or treble this number successfully, because with a large number, all the difficulties which arise, such as want of cleanliness, the pres-

Fig. 2.—PLAN OF POULTRY FENCE.

ence of vermin, impure air and risk of infection increase in a much larger ratio than does the number in the flock. But if one has succeeded with a small flock there is no reason why he should not be able to do so with several flocks, if each is kept in just the same manner as the original one. Afterwards the flocks may be enlarged, but as this is the very point on which most of the younger poultry fanciers fail, the greatest caution should be observed in adding to the number of fowls kept in each coop or house and yard. An inquiry is made by one who is desirous of keeping fowls upon a farm of thirty acres which has a stream passing through the middle of it, as shown in the plan in fig. 1, which is given as a good method of dividing it and arranging the yards and houses. From considerable experience with a similar plot of ground, we would suggest that the thirty acres be laid out in lots of two acres each as shown. The dwelling and orchard lots in the center would contain two acres, and each of the acre lots on either side of the stream would have a yard or "run" fenced off and kept in grass for grazing. The houses would be ranged, each in its yard, on both sides of

the stream, as shown, and a plentiful supply of water would be always at hand. A yard is behind each house; the yards behind the dwelling may be used for brood coops in which the young chicks

Fig. 1.—PLAN OF POULTRY FARM OF THIRTY ACRES.

would be near at hand. The fences between the yards may be of pickets or wire; the latter would be preferable if it could be afforded. A very complete arrangement of wire fence is shown in figure 2, and one for a small coop and covered yard in figure 3; a range of houses of very convenient shape and size, which may be left open or enclosed with yards, is shown in figure 4. It would be proper to keep each lot securely fenced, so that the flocks

Fig. 3.—COOP AND COVERED YARD.

could not mix, and not to keep more than fifty or sixty fowls in each plot. It would be better to begin with twenty-five at first, which would be enough until it was found safe by experience to gradually increase the number in the flocks.

**Milk as Poultry Food.**—We have been trying milk as poultry food during the winter and can confidently recommend it to villagers and farmers who keep one or more cows for family use. Where butter is made and skim milk is plenty, it is a very valuable addition to the fare of the poultry yard. One main difference between winter and spring laying is owing to the absence of animal food in winter. The milk supplies this, and is devoured with eagerness. The skim and buttermilk may be poured into the feeding trough, and kept constantly by the fowls, or it may be mixed with scalded meal of various grains. Indian meal is a good ration once a day, but it should be varied with oat or rye meal, and with whole grain of wheat, buckwheat, or barley. In a warm room with a good southern exposure, and plenty of light, there is no difficulty in getting plenty of eggs from early pullets, and this is the time when eggs are of great market value. Later in the season, when the broods

Fig. 4.—RANGE OF POULTRY HOUSES.

come off, milk, which will then be more abundant, will be an excellent feed for chickens, turkeys, and all kinds of young poultry, and will give quite as good returns as when fed to pigs.

### Another Inside Door Fastening.

Last month we published three forms of inside fastenings for double barn doors, all of which were constructed of wood. H. Minton, Morris Co., N. J., hands us a sketch of another fastener, that is constructed of iron, and is highly recommended

AN IRON INSIDE DOOR FASTENER.

by Mr. M., and others, who have it in use in his neighborhood. The long iron rod running the whole length of the door, is 1/2-inch in diameter, and fastened to the inside of the door by three iron strips, as shown in the engraving. The ends of the rod are so bent that they act as hooks, passing around 1/4-inch iron pins, driven one at the bottom, and the other at the top of the door frame. The rod is turned by a small lever near the center, which acts as a pivot, and is put in a rest when the door is fastened. Any blacksmith can make the rod for this very convenient barn-door fastening.

### What Shall We Raise?

The question above given interests every farmer, but especially those of us who live in the older portions of the country, where "farming don't pay," is so often asserted, and so often illustrated by those who assert it. The State Board of Agriculture of Massachusetts, held its winter meeting in December last, at Greenfield, in Franklin Co., in the N. W. part of the State. Those of us who attended from other States, found much to interest and instruct. The excellent dairy show held at that time, has been described in "Among the Farmers." A most interesting part of the proceedings, was a paper on the Agriculture of Franklin Co., founded upon the U. S. Census of 1840, and the State Census of 1875, and pointed out the changes that had taken place in the farm production, during 35 years. I wish that this paper could be read and considered, not only by every New England farmer, but by every farmer in all of the older States, where the farming of 50 years ago no longer "pays." The experience of the farmers in Franklin Co. shows that if "the times" change, we must change with them, and if one crop does not pay, we must then grow another that will. It appears from the paper referred to, that there are only five crops cultivated in Franklin Co., that show any substantial increase in the interval of 35 years. These are poultry, which rose from \$9,678, to \$31,155; hay increased from 43,853, to 61,056 tons; tobacco, from 600 lbs to 1,997,091 lbs.; dairy products, from \$165,765, to \$424,042. Broom corn is a new crop in the county, and only amounted to 13,579 pounds. Besides

these crops which have increased, neat cattle, horses, and corn, show but a slight falling off, and may be considered fairly paying crops. There is a great falling off in the number of sheep, but the large increase in their value per head, and in the value of lambs sold for market, would probably make sheep raising a paying industry. In nearly all other farm animals and crops, there is a large falling off in production, showing that farmers do not consider it profitable to raise them. Swine, wheat, and rye, have fallen off nearly 200 per cent, oats more than 300, and potatoes, 100 per cent. The increase in poultry is about 300 per cent, dairy products about 400, orchard products 500, and tobacco still larger. Franklin County is in the heart of the New England dairy region, and probably shows as fairly as any county, the drift of eastern agriculture. The fair inference is that farmers are abandoning these crops which show so large a decrease, because they are unprofitable. Agriculture in the older States, is in a transition state, and we are slowly feeling our way to a better husbandry. The progress is very slow, but we are confident it is very sure. So much light is breaking out from our agricultural journals, our State and County Fairs, and our Farmer's Conventions, that we can not always grow crops that run us in debt, because our fathers grew them. We must inevitably get out of the ruts. Nothing could show more clearly than these statistics, the folly of raising crops that do not pay. Pork raising for the general market, does not pay, and it has fallen off 200 per cent in 35 years. Why, then, should we undertake to raise any more pork, than will supply the family? The raising of poultry does pay, for it has increased 200 per cent. Why should we not invest our capital and labor, in that which experience shows, pays well. A farmer with a good range, can raise a ton of turkeys, at much less cost than he can raise a ton of pork. The ton of pork would be worth in the village market this year, about six cents a pound, or \$120.00 a ton. The turkeys eighteen cents, or \$360.00. Why not raise turkeys? And so, of the other things that are proved to be profitable. Let us get out of the ruts, and raise those crops that are promptly called for. Farmers should keep a keen eye on the markets, and see which way the popular taste is tending, and plant, sow, breed, and in every way plan to meet the demands of the times.

### Racks for Feeding in Yards.

The season for yard feeding is coming on, and some considerations about racks will be useful. The form of rack is important, because on that depends, in a great measure, the economy in the use of fodder. Frequently a large portion of the fodder is pulled out under foot and wasted; it is, therefore, necessary to provide against this in making the rack. Cows are quarrelsome and selfish, and it is instructive to see one filled and satisfied, but still

Fig. 1.—A SQUARE FEEDING RACK.

remaining in front of the rack so as to prevent her hungry sisters from getting a mouthful. This has to be provided against, so that each may get a share. A rack especially designed for this latter case is shown in figure 1. This is made of four stout chestnut or oak posts, 5 feet high. Lighter

cross-bars are fitted in 2-inch holes, as shown in the engraving, to a height of 30 inches, and close enough together as to prevent the fodder from being pushed out. Above these two, other cross-bars are fitted for the purpose of preventing the cows from pushing each other from the feed. A long rack, in which green clover, oats, or hay, can be fed is shown in figure 2. This is made of posts at proper intervals, and strips of boards or planks, 6 inches wide, spiked or bolted to the posts. A double rack is made in the middle, in which the fodder is placed. A rack for feeding meal, grain,

Fig. 2.—A LONG RACK FOR FEEDING.

or chaff, to cows or sheep, is shown in figure 3. This has a double slide, or hopper, the bottom of which is 3 inches or so above the floor of the rack, thus leaving a space for the feed to fall upon the level bottom from which the animals can readily eat it.

**An Agricultural Creed.**—It may be well to put down in black and white just what one thinks of any particular thing or class of things, and it may lead to good results if we subscribe to some

Fig. 3.—RACK FOR FEEDING MEAL.

formulated statement of the importance, and the varied demands of the best farming. At any rate this seems to have been the view of some of the agriculturists of Canada, who met in a convention and adopted for themselves the following *Agricultural Creed*: "We believe in small farms and thorough cultivation; we believe that the soil lives to eat as well as its owner, and ought, therefore to be well manured; we believe in going to the bottom of things, and therefore deep plowing, and enough of it—all the better if it is a subsoil plow; we believe in large crops which leave the land better than they found it, making both the farm and the farmer rich at once; we believe that every farm should own a good farmer; we believe that the fertilizer of any soil is a spirit of industry, enterprise and intelligence; without these lime, gypsum and guano would be of little use; we believe in good fences, good farm-houses, good orchards and good children enough to gather the fruit; we believe in a clean kitchen, a neat wife in it, a clean cupboard, a clean dairy and a clear conscience; we believe that asking a man's advice is not stooping, but of much benefit; we believe that to keep a place for every thing and every thing in its place, saves many a step, and is pretty sure to lead to good tools and to keeping them in good order; we believe that kindness to stock, like good shelter, is saving of fodder; we believe that it is a good thing to keep an eye on experiments, and note all, good and bad; that it is a good rule to sell grain when it is ready; we believe in producing the best butter and cheese, and marketing it when it is ready?"

### The New Varieties of Coleus.

Plants with bright-colored or variegated foliage are of special value in this country, where our hot summers prevent us from doing much in the way of producing bedding effects with flowers. The intense heat that causes such a rapid development and short duration of flowers is, as a general thing, favorable to the growth and coloring of the leaves of the so-called "foliage plants." Among these plants the Coleus stands at the head; the old Vel-

shade by the new varieties offered this spring. Both Henry A. Dreer, of Phila., and Peter Henderson, of N. Y., have been raising seedlings, the one with some seed from Australia, and the other with seeds from *Coleus multicolor* and *Chameleon*, and the results obtained by both are among the marvels of horticulture. As we examined the specimens sent by Mr. Dreer last fall, and by Mr. Henderson this spring, we felt that any painting or colored engraving that should exactly reproduce them would be looked upon as a freak in color by

come among our most popular plants; if they fail to stand exposure, their usefulness will be limited to culture under glass. It is not easy to imagine a more beautiful sight than a greenhouse or conservatory would present if filled with well grown specimens of these new and wonderful Coleuses.

### A New Cape Bulb.

Last summer we saw in the grounds of Messrs. Woolson & Co. a plant quite strange to us; it

A COLLECTION OF NEW COLEUS LEAVES.

A NEW CAPE BULB (*Montbrettia Pottsi*).

vet Coleus, *C. Verschaffeltii*, introduced some 20 years ago, is as popular and valuable as ever; a bed of its rich velvety dark maroon foliage, in contrast with the green of the lawn, presents a combination and contrast of colors of which the eye never tires, and which is pleasing in a place so small that it is the only decoration, or in extended grounds where it comes in as a part of an elaborate design. It was some years after the introduction of this excellent old plant that any others were offered, but new varieties came after a time, and of late each year has brought its "set" of new Coleuses, some of great merit. While our climate brings out the beauty of some kinds, it is very severe on others. Many of the so-called "Golden" varieties, in which the leaves present rich maroon or crimson, and golden yellow in beautifully contrasted markings, so long as the plants are partially shaded, when exposed to the full sun lose their markings and become all of the darker color. There are a few exceptions to this, as in the "Shah"; its leaves are curiously divided or halved by the two colors, and retain their beauty admirably. But however beautiful and brilliant the older Coleuses, they are completely thrown into the

the artist rather than a true portrait of real leaves. In these new kinds the range of colors is surprising. Among yellows there are from rich cream through lemon to deep golden and orange; in reds from pale rose through every shade of carmine to scarlet on the one hand and crimson on the other, and deepening into maroon and chocolate; besides there are various lively tints of green. These colors are in veins, dots, blotches, and variously washed and blended in the most pleasing manner. All that our group of leaves from Mr. Henderson's varieties can do is to give the effect in light and shade, and show the general character of the markings; the picture must be filled out by imagination, and no effort of this can exceed the reality. Each of the florists named, after selecting from some thousands of seedlings, has some 50 varieties too good to discard. Like Mr. Ricketts with his wonderful grapes, their success has been "too unanimous," and they are overweighted with treasures. For descriptions of those that are offered, reference must be made to the catalogues. What will be their final place time only will show; if any considerable number retain half their present beauty when cultivated in the open ground, they will be-

might be described by comparing it to a miniature Gladiolus. We were so much pleased with its appearance that we brought away specimens for the sketches from which the accompanying engraving was made. The plant was introduced into Scotland long ago, some bulbs having been sent from the Cape of Good Hope to Mr. G. H. Potts, near Edinburgh, Scotland; here they were cultivated for many years, and it is only recently that it has received the attention of English cultivators. It turns out to be a *Montbrettia*, and in honor of the gentlemen who introduced it, is called *M. Pottsi*. It grows about two feet high, has plaited leaves, and a slender, wiry flower stalk which is often branched. The flowers are of a very dark, rich scarlet, quite close upon the stem, but not crowded, and turning to one side; they are an inch or more long, and of the shape shown in the engraving. One of its valuable qualities is the long time the flowers remain in perfection. It is useful for cut-flowers, as its spikes have not the stiffness and formality of some related plants, and its lasting qualities adapt it to this use. Though one would not expect to find a plant from the Cape hardy in our severe winters, it has proved so in England.

and will be tested in that respect here. In England it is much valued for pot culture. When this *Montbretia* becomes better known, we have no doubt it will be generally cultivated, as it has all the qualities which should make a plant popular.

### The Potato "Mammoth Pearl."

A few years ago, earliness was the quality most sought for in a new potato, and it was regarded as the highest praise to say that a variety was "a week earlier than the Early Rose." Earliness is desirable, but it is only one of the good qualities a potato should possess. Ready steam communication has nearly obliterated our "times and seasons" for vegetables, and so far as putting new potatoes on the market goes, that is done by the southern

have since changed residence several times, the descendants of the same stock are still in the garden. Rhubarb comes so early in spring; is so palatable and wholesome, whether stewed for sauce or made into pies, and sells so well in the village market, that no good housekeeper can afford to do without. As to varieties, after trying several later kinds, the "Myatts' Linnaeus" has the preference. It is large enough, is of excellent flavor, not too acid, easily cultivated, and prolific. A dozen roots planted three feet apart each way, will supply an ordinary family and leave a surplus to give away or sell. The roots ought to be divided in fall or very early spring once in four or five years. A single eye with a vigorous root will make a large stock in a single season. The stalks may be plucked the second year, only care should be taken that leaves

THE NEW POTATO "MAMMOTH PEARL."

grower, who will anticipate the northern market farmer weeks before he can dig his potatoes, no matter how early they may be. In fact, new potatoes appear in the New York market, before the New Jersey and Long Island growers have planted theirs. Of late, potato growers have given attention to health, keeping and eating qualities, uniformity of size and productiveness in a variety rather than its earliness. Last spring Mr. J. A. Everitt sent us a sample of his new variety, the "Mammoth Pearl," for trial; they were accompanied by claims for a yield that seemed improbable—yet the raiser was convinced of their truth for he had sent the potatoes to allow us to prove or disprove them. Before the potatoes could be planted, a horse had got loose in the night and helped himself to the "Mammoth Pearl," and there were only a few eyes saved from the wreck. These eyes were planted, and when the few hills were dug, they, as far as they went, bore out the claims for productiveness. But one is not justified in recommending a potato for general culture from his experience in raising a husbel, though that quantity will allow him to judge of the quality. The "Mammoth Pearl" is large, its general shape is shown in the engraving, which is about two-thirds the average size. Being usually flattened, no part of the interior is so far from the surface that it does not cook through equally, and when cooked is very white and mealy and of excellent quality. The skin is smooth and of remarkable whiteness; circular says, "whitest of any variety." The eyes are few and even with the surface. Its keeping qualities are all that can be desired. In the important matter of productiveness the raiser makes the claim that it is the "most productive of all varieties grown in America," and "yielding double or triple an ordinary kind." We might regard this as extravagant were it not supported by testimonials, in some cases from persons well known to us; what they say is supported by our own limited experience, so far as it goes, and we have no doubt that the "Mammoth Pearl" will take a high rank as a cropper. As to season, it is medium early, reaching maturity along in August.

**Rhubarb.**—Some thirty years ago, the writer procured for Hon. Marshall P. Wilder a few roots of "Myatts' Linnaeus" Rhubarb, and though we

enough remain on the plant to keep it in vigorous growth. For a new plantation of Rhubarb, select rich well drained soil well exposed to the sun. Much of the profit of growing it for market depends upon its earliness. It is a gross feeder, and should have abundant supplies of manure every fall or spring, forked in around the plants. There is no danger of making the ground too rich. It hears forcing well. The season may be anticipated three or four weeks, by putting a common hot-bed frame and sashes over the plants where they stand. Rhubarb comes at a season when the winter apples begin to fall and before the strawberries ripen. It ought to have a place in all our village and farm gardens. It starts with the crocus, and is among the earliest plants to welcome the spring.

### The Lettuce Mildew.

For a number of years the market gardeners in some localities have suffered more or less severely from the attacks of a mildew on their early or forced lettuce. This spring the numerous complaints led us to inquire into the trouble, which had reached

Fig. 1.—SECTION OF LEAF WITH MILDREW.

such magnitude, that one gardener assured us that it was taking away from him, and those engaged in the same business around him, the source of their very living. The following circular was addressed to many of the leading growers of early lettuce, Secretaries of State Horticultural Societies and others from whom information could be gained:

245 BROADWAY, NEW YORK, Jan. 14th, 1880.

"Dear Sir.—In order to become more thoroughly acquainted with the prevalence of the Lettuce Dis-

ease, the following questions are proposed. It is desired that they receive the early attention that the importance of the subject demands:

1. Have you been troubled with any disease of your lettuce, and if so to what extent?
2. So far as you can judge, what is the nature of the disease?
3. What part of the plant is first affected, and what are the conditions of the weather, soil, etc., when the disease prevails?
4. Have you tried any remedies; if so, what, and with what results?
5. Are some varieties of lettuce more susceptible than others?

Please add any other information on the subject that may not fall under the above questions, and greatly oblige, etc."

From the responses to these questions we infer that the Lettuce Disease is at present confined to

Fig. 2.—TIPS OF BRANCHES.

the Atlantic States, and that it is most prevalent in those localities where lettuce has been grown upon the same ground for a considerable length of time. There is no doubt but that it is a fungus, as a microscopic examination of the specimens from Newark and Jersey City both abundantly show; in fact the mildew upon the lettuce is not a new thing, it having been described a number of years ago. It first manifests itself upon the older and outer leaves as a fine frosty coating, soon causing the leaves to turn dark-colored, wilt down, and rot away.

The Lettuce fungus is a near relative of the grape mildew, belonging, as it does, to the same genus of parasitic pests. In general structure, methods of growth, and propagation, it is therefore much like that of the mildew of the grape, which was fully described in the *American Agriculturist* for September, 1879. It is to be remembered that these mildews are exceedingly small, and in presenting any illustrations of them they can only be those of greatly magnified views. When the actual surface of the lettuce leaf is examined with a hand lens, the white substance resolves itself into a miniature forest of small stems and branches.

In figure 1 a highly magnified view of a cross section of the lettuce leaf is shown, with a single mildew branch, passing out of a breathing pore of the leaf where it divides quite regularly and forms a tree-like top. The tips of the branches are of a peculiar star-like form, and from the radiating points the spores (or seed-like bodies) are formed and when ripe are easily detached.

Figure 2 shows a much higher magnified view of two of these ultimate branches with a single separated spore drawn on a still larger scale.

The portion of the fungus beneath the surface of the lettuce leaf consists of winding threads which, as they pass between the cells of the lettuce tissue, form projections that pass through the cell walls and serve as *suckers* to absorb the substance of the cells. A highly magnified view of a small portion of an embedded thread is shown in figure 3. This is the real nature of the trouble, a multitude—a forest so to speak—of small plants, living upon and drawing away the very life of the lettuce.

In the way of remedies we have, up to the present time, but little to suggest. The fact that the trouble is in nature very similar to the grape mildew, and that the use of Flowers of Sulphur has proved the most effectual in the latter case, it is to be presumed that it also is the remedy for the lettuce mould. There is this difficulty in the use of Sulphur in the case of lettuce; the foliage is the portion both dusted and eaten, and unless the leaves are thoroughly washed—as they ought to

Fig. 3.—PORTION OF FILAMENT.

be any way—a sense or suspicion of eating sulphur would be developed that would tend to greatly diminish the consumption of this excellent green food. Lime sprinkled upon the plants has proved of considerable value in some cases as our correspondence indicates. In those localities, or rather on that soil, where the crop has been ruined, it is suggested that the growth of lettuce be abandoned for a time, for there is no doubt but that the soil has become foul, so to speak, and an absence of the lettuce plant is essential to the eradication, by death by *starvation*, of the minute fungus spores.

### Have You a Strawberry Bed?

This question is put to every reader who has the land, and especially to every farmer, who, having the land, is very apt to not have strawberries. Without taking space to inquire why the farmer, who of all others should have an abundance, so generally has no strawberries, we put in our plea for his family, and insist that he shall provide them with this excellent fruit—not only a few as a luxury, but an abundance. There is just one time to make a strawberry bed, and that time is now! Under any circumstances a strawberry plant must grow a season before it will give a crop; there is no way in which plants may be set this spring and give fruit the same season. If any “nursery agent” offers such—don’t buy them. Much that has been said about strawberry culture has conveyed the impression that it is a great deal of trouble; that runners have to be cut off and much care given otherwise, while in fact it is no more trouble to raise strawberries, than it is to grow earrots. But the cost? Is very little—nothing compared with the result in fruit. One can begin as small as he pleases; if he can not afford the outlay for a large bed, let him buy enough for a start and raise his own plants. It makes no difference where the farmer may be, if he gets the *American Agriculturist*, he can have strawberry plants—the mail brings both. A dozen, or a hundred plants come by mail, and when one has even but a dozen plants, his strawberry future is provided for. “It is the first step which costs” is a proverb. In this case “it is the first step which tells.” While we have in view especially the family comfort, it may be well to consider that in most localities enough berries can be sold from the first crop to pay for the whole outlay—only don’t sell and let the family go without, but have enough for both demands.

“How many shall I plant?” will be one of the first questions to decide. An ordinary family should have at least 200 plants, and generally 400 will not be found too many if the fruit is used freely. It is better to provide for an abundance.

**What kinds?**—If restricted to one kind, we have no hesitation in saying, Charles Downing. If there are successful strawberry growers in the vicinity, find what does best with them and plant the same kind. But we do not advise planting all of one kind. If 400 plants are set there may safely be four kinds. Charles Downing, Monarch of the West, Champion, and Sharpless, would be a good selection, but it may be varied and not go amiss.

**How to Plant.**—Select a good bit of soil, all the better if it was in potatoes last year, and if practicable within sight of the house, and prepare it just as you would for a good crop of cabbages; this means an abundance of the best manure well worked in. Mark out the rows two feet apart, three if a cultivator is to be used, and set the plants one foot apart in the row, using a trowel to open the ground, and when the plant is put in, crowd the soil down firmly over the roots with both hands. Thereafter run the cultivator, hoe, or rake, often enough to make the soil mellow and keep down the weeds. The plants will by and by throw out runners; turn them into the row and let them take root. For the after treatment of the bed, consult “Notes about Work” at the proper season.

**Raising Plants.**—If it is preferred to buy a few plants to start with and raise a stock to put out next year, set these two feet apart each way, and let runners form. Ashes are very useful to promote a large growth of runners. Finally, plant strawberries—and be sure to do it this spring.

### That Grape Vine.

Two years ago (1878), knowing that there must be few, if any, among our readers, who could not somewhere find a place for a grape vine, we insisted that one vine at least, should be planted, wherever there was a bit of soil, no matter if it were in the smallest of village or city back-yards. In a series of articles headed, “One Grape Vine,” we gave minute directions for its planting, and showed how it would grow through the summer, and what should be done with it. That these articles led to the planting of a great many vines, our correspondence shows, and even now we have letters, asking advice as to that “One Grape Vine.” The greatest number of letters at the present season, are with regard to pruning and training, and they especially ask as to the treatment of old and neglected vines. Pruning ought to be done in the fall, or in the very early spring, long before the swelling of the buds shows that vegetation has started. If the vine is cut after root action has commenced, there is a flow of sap so copious, that it is popularly called “bleeding.” While there is a great difference of opinion, as to the injury resulting from bleeding, we are confident that it can do no good, and it is better to avoid it. A grape vine is so tractable, that it

Fig. 1.—A CANE. Fig. 2.—THE SAME IN GROWTH.

may be perfectly adapted to a great many places, if we only direct it properly, and to do this, we must learn a few things about its growth, and work in accordance with them. If one clearly understands the manner in which the vine—every grape vine—grows, all mystery and difficulty will disappear. One important point—and one which many who see a vine daily fail to observe, is this: the fruit is always borne upon a shoot of the *present year's growth*. To understand this, let figure 1 represent a young vine, or a branch of an old one, large or small. This branch grew last season, and is just as it was left when the leaves dropped last fall, and as it will be before growth starts this spring. The vine is seen to be in sections or joints; there is a bud, a piece of vine, longer or shorter, according to the variety, or the luxuriance of growth, then another bud, with a piece of vine, and so on, for the whole length. Observe that no two successive buds are upon the same side of the vine; if bud No. 1 is on the right side, No. 2 will be at the left side; No. 3 right, and so on alternating, for the whole length. Unless they have been removed, or accidentally broken off, there will be *opposite* each bud, a tendril, or the remains of a stem which bore a cluster the season before. These points where the buds are placed, are properly joints, but we commonly give that name to the portion of vine between two buds, and speak of a variety as “short-jointed” or “long-jointed.” The botanists name, for this portion of the stem

Fig. 3.—CUT BACK.

where the bud is placed, is *node*—a not difficult name and one that has a definite application. Every branch of vine a year old, or *cane*, as it is called, has its *nodes*, with a bud and a tendril or remains of a cluster at each, and these nodes are separated by longer or shorter joints or *internodes*. When growth

Fig. 4.—THE CANE, FIG. 1, LAID DOWN.

starts in figure 1, the buds will swell, burst open, and a small, tender shoot will begin to lengthen. Examine this young growth; when but a few inches long it will be seen to have nodes and internodes; and at each node a leaf, opposite which is a tendril or a cluster of minute buds, which look like and are often taken for young grapes.

If the cane (figure 1) is untouched, but allowed to grow just as it is, it will soon appear as in figure 2. A shoot coming from each bud, the uppermost shoots, the tendency of the sap being towards these, will be the most vigorous and will grow away rapidly, robbing those below of food. The lower shoots will in this case be smaller and weaker, and some of the lowest buds may not start at all. It will be seen that if a vine is left to itself year after year, the most vigorous shoots, those which bear the fruit, will be further and further away from the root, and the vine will become a tangled mass of weak stems. If instead of allowing the vine (figure 1) to have its own way, we cut it off where the cross line is placed, all the nutriment that would have gone to several shoots will go to the two that remain, and we shall have instead of a vine, like figure 2, one as in figure 3, where there are two strong shoots, bearing their fruit buds down where they are within reach and being better fed, both leaves and fruit, and the shoot itself, will be altogether larger, and more vigorous and healthy. If instead of cutting off figure 1, as here described, we bend it down and fasten it in a horizontal position before growth begins, we shall change the condition of things: the shoots from a more equal distribution of food—or sap—will start more alike; the uppermost can not rob the others. In practice, in making an *arm* in this way, all the buds are not allowed to grow, as they would be too much crowded; but this diagram is merely to illustrate the principle. Let us now suppose that instead of cutting figure 1 back, as in figure 3, or bending it down as in figure 4, we want our vine higher—as soon as the buds have started

Fig. 5.—SHOOTS HIGH UP.

and have grown an inch or two, we rub or break off all but the two or three topmost buds, as the case may be, and the shoots from these may be carried out horizontally, as in figure 5, or continued in an upright direction as we may prefer. These illustrations are sufficient to show how easily a vine may be controlled and placed where we wish it. Observe that each shoot is but a repetition of the original cane, and that each shoot, when ripe in the fall, will become a cane like figure 1. By fixing these points in the mind: that the growing vine is made up of a succession of joints, furnished at intervals with a leaf and opposite this a tendril or a cluster of grapes, and that these alternate, the matter becomes very simple. The management of the growing shoots must be left for another month.

## THE HOUSEHOLD.

For other Household Items see "Basket" pages.

### A Framed Calendar.

The almanac, formerly regarded as one of the necessities of every household has in great measure given place to the calendar. The ordinary almanac contains much more than one has any use for, and the trouble of turning to the month and day is avoided by using a tablet calendar, or one which gives the whole year on a single page. Calendars are numerous, the various insurance companies, patent medicine men, and even merchants sending them out in great abundance, for the purpose of

A NEAT AND CONVENIENT CALENDAR.

keeping their names and their business before the eyes of the public. But we do not care to be told that some wizard's "gargling oil" is the only limb preserver in the world, or that life depends upon the use of somebody's pills, especially if we have a regard for our family physician. A year of advertising upon our walls of any thing, no matter how good, is more than we care to give in exchange for a calendar. A calendar can be provided which has none of these objectionable qualities, but may be a real ornament to the room, as well as a convenience to the household. The accompanying engraving suggests such an one that may be constructed by any one who has a taste for home decoration. It consists of a plain card-calendar, which may be prepared from any one of many of those which are so freely distributed, by cutting off the objectionable surrounding border, and leaving a simple truthful card of the months and days. This card is then to be set in a neat frame, which may be constructed in a variety of ways, and of a number of different materials; in fact it allows of the exercise of a wide range of taste.

The one shown consists largely of the scales of pine cones with clusters of acorns, scattered here and there. For such a frame a foundation of heavy card-board is required which is cut in outline to correspond to that desired in the finished frame, to which the scales are sewed with stout silk thread. As a protection from flies and dust it will be well to cover the calendar with a sheet of glass, which can be secured to the foundation pasteboard by bits of wire or small strips of tin at the four corners, which are hid from view, as is the entire outline of the glass, by the overlapping pine scales. When constructed a handsome finish may be produced by giving the frame a coat or two of varnish.

**Bits of Soap.**—It was once noticed that a cook, who was neat and economical, kept a tin can on her

kitchen dresser from which tomatoes had been emptied. Farther inquiry revealed the fact that it was the receptacle for little odds and ends of soap that had become too small to use in washing. Occasionally, water was added, and the contents put upon the stove until they melted. Thus a tin of soft soap to be used in dish washing was manufactured from scraps that are generally thrown away.

### Look Well to the Pork Barrel.

The large amount of tainted, "rusty" pork that is consumed every year is sufficient evidence that it is not, in many cases, packed in a proper manner. That pork may be kept sweet and good, care and good judgment must be exercised. In the first

place the barrel into which pork is placed must be perfectly clean. It should be subjected to a scalding as thorough as the neat dairy-maid gives her pails and pans. The old brine will be good to use again if it is boiled and all impurities removed by skimming. The salt used for packing ought always to be the best coarse kind. The pork should never be cut up or laid in the barrel until perfectly cool, but not frozen. The pieces should be so cut that the barrel can be closely filled in regular layers. Put on plenty of salt between the layers, and after a few days pour on the brine until the meat is entirely covered, when a close-fitting board is put on and kept down in the brine by a large stone. This board and weight should always be re-

placed after having taken out pork, and kept on at all other times. The pork, to insure good keeping, must always be submerged in the brine. Keep the pork barrel in a cool place, and let the brine be always saturated, *i. e.*, so it can take up no more salt.

### Hints on Household Matters.

BY A DELAWARE HOUSE-KEEPER.

**MENDING A CARPET.**—My dining-room carpet was only a rag carpet to begin with: latterly it had become a ragged one. I was contemplating it ruefully one day, knowing that the state of my purse would not allow me to replace it just yet with a new one. I could think of no way to mend it, but by big patches tacked in place. In the midst of my dilemma an experienced old lady entered, who suggested paste instead of tacks. "I have repeatedly put muslin patches over the carpet with paste," said she, "and it is surprising how well it holds." I took the hint. Patches are not, in their nature, beautiful, yet a patched garment is decidedly better-looking than a ragged one, and the same is true of a patched carpet, and my patches were so easily applied and proved so adhesive, that I rarely sweep the room without a mental benediction upon the one who suggested it.

**CUTTING HOT BREAD.**—One day company arrived unexpectedly. Supper was just over and no bread had been left. I had just taken from the oven some delicious-looking light bread, but it was too hot to cut. We live in a country place where there is no baker. In my bewilderment, I happened to remember that in Mrs. Whitney's Cook Book "Just How," she suggests heating a knife, in order to split open a hot short-cake. Why, thought I, may not smoking-hot light bread, be sliced with a hot knife! It is the cold surface of the steel applied to the warm dough that produces a disagree-

able clamminess. I heated my carving knife and tried it. The bread sliced beautifully, and as I piled it up to bring to the table, I put it on a plate upon which I had laid a fresh napkin, for the contact of the hot bread with the cold plate would have produced the same sodden clamminess on the surface of the lower slice. Of course, I would not recommend the slicing of hot loaves except upon emergencies. As a frequent diet it might prove injurious, but not more so than other warm breads.

**PUTTING AWAY TUBS.**—A very little thing, yet worth knowing. One week my regular washer woman could not come, but sent a substitute. When she returned, on the following week, I found her tugging away at a nest of tubs, finding it almost impossible to pull the inner one, from the enclasping outer one. "I never have this trouble," said she, "when I put the tubs away myself."—"How do you avoid it?" I questioned.—"Why do you not see she has put all the handles in a straight line. Now I always set them away, so that no two handles shall come together. Then, if they do swell I can have thorough use of the handles, and with them the tubs are soon separated."

**TURNIPS ON THE GRIDDLE.**—I had seen for some time a statement going the rounds of newspapers, that a turnip used in rubbing the griddle, while cooking griddle-cakes, would give the desired smoothness and do away with the unpleasant smoke. I doubted it, but a trial soon convinced me that the statement was correct. I found, however, that at times, it was necessary, when beginning, to put a very little grease on the turnip, but this made no appreciable smoke.

**RIGHT AND LEFT.**—My little boy was left-handed. I had found, by experience, that school-life would be particularly irksome to him, if that defect were not remedied before he began school. It was useless for me to try to persuade him to draw pictures on his little slate with the right hand. That hand was really weaker than the other; he could not guide it. So I made little pictures on the slate, nothing intricate, then rubbed them off with my finger till only the dim outline could be seen. These I required him to trace. The weak hand that could not originate a line, could, little by little, approximate the rubbed outlines. Afterwards, by the same plan, I taught him to write the letters of the alphabet, and by the time he was old enough to go to school, he had learned to use his right hand.

**A BABY TENDER.**—My baby was creeping all over the floor, and I had no nurse for her. There were times when she drove me nearly distracted. When I was busiest, it seemed to me she crept into the most dangerous places. Just imagine a woman, busy preparing dinner. Except herself, baby is the only occupant of the room. She opens the oven to baste the roasting beef. Just as her entire energies are directed to the operation, baby takes advantage of her stooping position and creeps up on her back. She cannot dislodge the child, and it is with extreme difficulty that she replaces the hot pan without an accident. I frequently found myself in such positions. At last I thought of a remedy, I procured a dry-goods box, or such a box as shoes are generally packed in; its dimensions were as follows: depth half a yard, width fifteen inches, and length one yard. This I put in one corner of the kitchen. Whenever I was particularly busy, I caught up the darling and boxed her. She might dislike her close quarters, might struggle to be free, but at least she was safe. But in a little while she did not dislike her prison. She learned to pull up by the sides and look over; she took her first steps supported by its sides, which were at a convenient distance apart; hie and bye, she would walk from end to end in her efforts to be near me as I moved about the room. But it is a clumsy affair. I shall have a much better one for the sitting room: it is to be made of the same dimensions but simply a skeleton frame, except that the floor is to be solid. Upon this frame, which is to be very smooth around the top, I shall tack wire-gauze; the entire structure is to be on casters, that I may easily roll it about, a long flexible strip is to be tacked from side to side like a basket-handle. From this, I shall suspend the toys I find amuse

her, and I rather think my home-made Baby Tender will be a comfort. Some bright bits of Brussels carpet, which I have been saving, will, when nicely bound, come in place as a rug for baby's box.

### Household Notes and Queries.

**PUTTING DOWN CARPETS.**—One of the most tiresome incidents of house cleaning, is the putting of the carpet upon the floor, and so much depends upon its being done well, that it is a matter of no little anxiety with many neat house-keepers.

A CARPET STRETCHER.

The stretching of the carpet so that it will fit closely to the floor, is the important point. Carpet stretchers of various kinds, may be had at the stores, at greater or less cost, but a home-made one can be constructed in a few minutes, and at little or no outlay. This is made, as shown in the engraving, by nailing a short piece of hard-wood to a suitable handle; into this piece, or head, a number of nails are driven, and afterwards sharpened with a file, to form teeth which will catch hold of the carpet. The stretcher thus made, is to be used with a pushing motion, and it will be found to save much strength, keep knuckles from getting sore, and the back from many an ache.

**STOVES, AND THEIR TAKING DOWN,** will soon occupy the attention of house-keepers. In many dwellings, the stoves, with the exception of that in the kitchen, are all taken down, and put out of the way at house-cleaning time, and before the end of this month, there will be many a cold sitting room, and generally desolate, not to say sick, household, from this very reason. There are pleasant days in April, and warm, sultry ones in May, but they are followed by cold spells, which call, and often loudly, for a fire in the room, for the comfort and health of the inmates. Of course a stove takes up some space, and a room with the stove removed is more capacious, but when space is obtained at the expense of all comfort in the room, it is bought too dearly. Both comfort and health are in favor of the old principle, of not taking down the stove until its use is at an end, be it at the end of June, or when the stove is worn out. In our changeable climate there is hardly a month without a day on which a little fire at night, or in early morning, is not desirable, especially for invalids, and there should be some room, other than the kitchen, where one may be started at a moment's notice.

**IS RHUBARB WHOLESOME?**—Every once in a while there appears a newspaper paragraph stating that the acidity of Rhubarb stalks is due to Oxalic Acid, and therefore poisonous. This would be "important if true," but fortunately for those who find in Rhubarb a most acceptable substitute for fruit, it is not true. The acidity is due to a mixture of Malic and Citric acids; the one being the acid of apples and the other the acid of lemons.

### Mildew on Cotton Cloth.

Every house-keeper is aware that the unwelcome dark spots known as Mildew, are more apt to appear upon articles of cotton or linen that are starched than upon those which have not been so treated. All cotton goods are starched in their manufacture, indeed before they are manufactured in the sense of being woven. The yarn, as the threads are called, whether it is to form the "weft" or "woof" of the fabric, is "sized" as it is termed, which is simply dressing the yarn with a paste of some form of starch; the fine threads which are wound upon one roller are transferred to another roller that is placed several feet distant from the first. As the threads or yarn slowly pass from one roller, the

paste or "size" is applied by means of a brush. The sizing thus applied to a certain extent strengthens the threads, and as it makes them vastly more manageable in the process of weaving it is a proper thing to do. But some weavers having learned that a sized thread was a great deal larger than one not sized, have shown much ingenuity in coating a small thread with a great deal of size, and not only this, but have contrived to add to the sizing China Clay and other substances, and thus coat the threads with a large amount of foreign matter. Cloth woven of such threads, while it appears very close and heavy, when washed loses all this filling and appears in its real character—a poor, thin, slazy stuff, quite unlike that for which it was bought. English manufacturers, especially, have carried on this excessive sizing and filling with goods for the Eastern markets, and for the half savage people in Africa and elsewhere to an enormous extent. One of the first things such people buy is cotton cloth, and wherever American cottons, with only the necessary amount of sizing have appeared in competition with the oversized stuffs, the latter have been driven out of the market. But another trouble has come upon the makers and sellers of highly sized stuffs; they have proved to be highly susceptible to mildew, and great losses have been sustained on account of the injury from this cause. Indeed so important has this matter become to English manufacturers that

A MAGNIFIED VIEW OF CLOTH WITH MILDEW.

a book has recently appeared for their benefit, entitled "Sizing and Mildew in Cotton Goods." We have often shown that the plant mildews, like those of the grape, lettuce, etc., and the various moulds, are really a minute vegetable growth, consisting of plants, so small as to only be seen when highly magnified, but just as much plants as a cabbage or an oak, and like these larger plants they must have something to live upon. The leaf, and other part of the plant bearing these mildews and moulds, are fed upon by these minute plants and their substance broken up and destroyed; so with the cloth mildew; it feeds upon the starch used in sizing, and if it does not feed upon the fibre of the cloth itself, it so injures it as to cause it to decay and become worthless. We may look upon the injury mildew causes these oversized cotton goods without any very great regret, as it is one of many ways of expressing the fact that "honesty is the best policy," and may even find in the mildew a beauty which the dishonest manufacturer fails to see. The work referred to gives illustrations of the mildew as seen by the microscope, one of which is here reproduced. The engraving shows a highly magnified bit of mildewed cloth, in which the threads are shown very large, with the various kinds of mildew plants running over and among them as irregular twisted and knotted lines. "No less than 27 different kinds of moulds and mildews have been detected on cotton cloths." The mildews which annoy the house-keeper are similar in appearance to those here shown. The best preventive of mildew is dryness, as the minute plants can not appear

and make their growth without a certain amount of moisture. Fabrics that are to remain for a long time unused should be put away without first starching.

### Work with Scroll or Fret Saws.

Within a few years, scroll or fret-saws have been brought to a great perfection, and the use of them, is to some a profitable employment, while to others it affords an attractive and pleasing pastime. The products of the scroll-saw are becoming frequent in household conveniences, and in the decorations of the parlor and drawing room. The windows of store-keepers who deal in these goods, present finely, and frequently elaborately wrought designs on exhibition, which are truly works of art. In the accompanying engravings, two specimens of scroll-work are given—those that workmen of average skill could make in a short time.

Fig. 1.—PICTURE FRAME.

The design in figure 1, is for a carved frame for a cabinet photograph, some small painting, or other picture, the whole to rest on an easel, wrought from the same kind of wood. Figure 2 shows an easel of an elaborate design, with the picture itself in scroll-work. The number of designs, of which those given are but samples, is limited only by the skill of the artist, and that of the workman at the saw. The dealers in scroll-saws, have a very large assortment of suggestive designs, which they distribute freely in the form of sheets and catalogues—and of themselves make a very pretty collection. The uses to which scroll-work can be put in the household, are various; wall pockets, thermometer frames, brackets, card baskets, lamp mats, toilet cases, card holders, etc., etc., are but a few of the many. Those designs that are purely for ornament, can be used to decorate the windows by suspending these near the glass by a fine thread, where they show off to good advantage, both from within and without. But in order to get the very best effect, the scroll-work should be of the whitest of wood, and then provided with a black back-ground. Merchants have in many cases availed themselves of the attractive and pleasing contrast thus produced, by putting their names, or those of their goods, in white-wood scroll-work, and then providing it with a black back-ground, in their shop windows, or show cases. In household decoration, nothing seems more appropriate than black velvet, but any other rich cloth of the same color would answer. Ornamental work like that shown in the engravings, may be of any size, but for ordinary mantels, a back-ground of a square foot in area, is the most acceptable. The whole, when completed, can be placed upon an easel. The low price of scroll saws puts them and their products within the reach of all.

Fig. 2.—EASEL AND PICTURE.

## BOYS &amp; GIRLS' COLUMNS.

## The Doctor's Talks.

If at play you accidentally run against another boy, you may hurt him, may even throw him down with great violence. But how is it with yourself? I recollect that in some play at ball or other game I ran against a boy I did not happen to see, and while he went down, I struck with such force as to "knock the breath from my body," and I suffered so much for a few seconds that I have never

Fig. 1.—DRIVING NAIL IN A SPRING BOARD.

forgotten it. The boy was standing still, I went against him with great force, sufficient to knock him down, and I was badly hurt. This is one of the earliest illustrations I can recollect of having learned of what is laid down in the books as one of the laws of motion, which is:

## ACTION AND REACTION ARE EQUAL.

If you strike the table with the hand, the table reacts with the same force. If you fire a ball from a gun, the explosion of the powder pushes the ball in one direction and the gun in another; the ball goes to a great distance, the gun moves but little. The force of the powder is spent in moving the gun, which is very much larger than the ball, and, if the gun is held close against the shoulder, is communicated to your body also. When you jump from a big rock, you push yourself with a certain force, and by the spring of your knees, etc., throw yourself to several feet away. Now you push the rock with the same force that you do yourself, and through that the whole

Fig. 2.—BLOCK UNDER END OF BOARD.

earth, but these are so vastly larger than yourself that the motion given to them by your jumping can not be measured. If, instead of a rock, you jump from a small boat, the case will be different, as the movement of the boat will plainly show; indeed, in even stepping from a small boat one has to be very careful else he will be a dripping illustration of the fact that "action and reaction are equal." We see this in the flight of a bird; the bird beats the air down with its wings, the air on the other hand reacts and raises the bird. In rowing, we push the oar against the water; the water in turn reacts against the oar, and the boat is sent through the water. In our talks about Matter and such things, we shall have use for a word, and it is one that we will now and then meet with, which is

## MOMENTUM.

If you look in the books to find what Momentum is, you will learn that it is "the mass of a body multiplied by its velocity,"—a perfectly correct definition, but one which may

not at first give you a clear idea as to what is meant by Momentum. If I were to say that it is "the amount of *go* there is in a body," it would not be very elegant, but perhaps you would understand it better. It is the force with which a body in motion strikes against another at rest. A stone will easily hold up a hammer; we may press the hammer against the stone as hard as we are able without changing the stone, but with a very quick blow of the same hammer we can break the stone at once; in other words, we have given momentum to the hammer head—and motion joined to weight will accomplish what weight alone failed to do.

## A SMALL BODY MOVING SWIFTLY

may have a greater momentum than a large one, going slowly. Even so light a body as air, when moving rapidly, exerts great force, as we see in a hurricane, and water in the form of hail, when rapidly moving, breaks the glass in our windows, and strips the small branches from trees. On the other hand, a large body, though it moves but slowly, has great momentum, and can strike with great force. A ship, moving so slowly that the motion can hardly be seen, will come against the pier with immense force, and if a small boat should chance to get between the two, it would be made into splinters at once. When a body in motion strikes another, it loses its own momentum, and imparts it to the other; if the second body is movable, it will be set in motion; if not, the effects of the blow will be seen in other ways. Boys in their early attempts with tools, learn some lesson about momentum. If they try to drive a nail into the free end of a board, as in figure 1, they find it very difficult; the force or momentum of the hammer does not send home the nail, but merely gives motion to the board; drive as furiously as you may, the nail will not go to its place. An older person may show you, or you may discover it yourself, that simply holding a block under the end of the board, as in fig. 2, will allow you to drive the nail at once. In this case you strike no heavier blows, use no more force. In the first case, the momentum of the hammer was used up in springing the board; in the second, it is received by the nail and block together, with the effect of driving in the nail.

## The Doctor's Correspondence.

## PASTE FOR SCRAP-BOOK.

"Sarah M. W., N. J.—Paste is much better for pasting your materials into a scrap-book than any kind of gum or mucilage. Stir the flour so thoroughly with cold water that there will be no lumps in it, and boil slowly for a few minutes; when cool stir in a few drops of carbolic acid to preserve it. Cressote is said to answer as well.... We have had first and last some very curious examples of insect work, but none that to me seems more wonderful than a bit of stick—a twig of a pear tree that had in it a deep groove three-fourths of the way through, and as nicely cut as if it had been put in a lathe and turned. The gentleman who sent it from Arkansas suspected that it was done by an insect, but he had never been able to catch any at work. He was right in thinking it to be the work of an insect, and for his benefit, as well as to call your attention to it, I give its portrait from Doct. Packard's "Guide to the Study of Insects." The workman, as you see, is a little beetle

## CALLED "THE GIRDLER,"

The engraving shows it at work; when the job is finished, the groove is more nicely done than most of you boys could do it with a knife. The insect was first described as long ago as 1825, it being then known to work upon hickory trees; but our Arkansas friend writes that pear trees are most attacked, its next choice is an apple

or hickory, and occasionally it attacks the cherry and plum. You do not need to be told that such grooves, however neatly made, are very injurious to a tree; it attacks stems as large as your finger, and of course all that part of the stem above the cut will die. They have not before been known to be abundant, but they seem so in the orchard of the gentleman who sent the specimen.

## WHY DOES THE INSECT DO THIS?

Some of you may think it is to get food, but the wood is not eaten; if that were the object, she—for it is always the female insect that does the work—could get wood without the trouble of cutting so deep. She does not do it to get food for herself, but to provide her young with food, which must be dead wood, and very curiously she does it. The mother insect makes holes in the twig in

A GIRDLER AT WORK.

which she places her eggs; afterwards she goes below the place where she has put the eggs and cuts this groove; in time the branch dies, and it being held by a very small neck of wood, the winds break it off, but the young Girdlers are all snug within, where they can feed upon dead wood until they have made their growth; in time they will appear as perfect Girdlers, to go on with the work. When the female insect has laid her eggs, and girdled the twig, she dies; she never lives to see her young, but she works on at her girdling, slowly making the groove, a minute chip at a time. Isn't it wonderful, this foreseeing the wants of her young and providing for them in this strange and peculiar manner!

## Our Puzzle-Box.

## WORD-MAKING PUZZLE.

(In the following lists of words, one word in each list is to have the letter at the end of the list added to it, and with it be transposed into another word.—*Example.* List:—boy, reprobate, ladder, rock, stone, reassurance, by; letter, H. The word in the list to which the letter H can be added, is—"stone;" with H, it can be transposed into *honest*.)

1. List: batter, fire, engine, gruel, sense, in, nonsense; letter—U.
2. List: muslin, embroidered, shirt, vest, house, apiece, toy; letter—T.
3. List: dread, Indians, bugbear, onto, mouth, cotton, adapt; letter—M.
4. List: copse, gate, letters, valued, bit, love, future, galley; letter—N.
5. List: history, tale, twice, mine, oyster, knife, incur; letter—V.
6. List: book, perusal, picture, incur, my, magic, gather; letter—E.
7. List: cow, student, cant, convoke, coo, hexagon, poetry, bond; letter—I.
8. List: open, volume, butcher, veal, suet, hearth, audit; letter—P.

## CROSS-WORD.

My first is in awful but not in grand,  
My second is in pasture but not in land,  
My third is in orange but not in plum,  
My fourth is in finger but not in thumb,  
My fifth is in chapter but not in verse,  
My sixth is in patient but not in nurse,  
My seventh is in prison but not in cell,  
My eighth is in clapper but not in bell,  
My ninth is in poison but not in hane,  
My tenth is in torture but not in pain,  
My eleventh is in cracker but not in hun,  
My twelfth is in pleasure but not in fun:  
And now you may look  
In your picture-book,  
And the first one you see  
Is sure to be me.

## NUMERICAL ENIGMAS.

I am composed of 16 letters:

- My 1, 6, 11, 10, 16, 5, is the name of a river.
- My 14, 12, 4, if you eat it will make you shiver.
- My 12, 2, 16, 4, 16, is what many like to eat.
- My 5, 13, 11, 10, is nothing but a cheat.
- My 12, 2, 7, 15, is a part of your face.
- My 11, 1, 6, 16, 8, 5, is the name of a place.
- My 8, 11, 10, 4, is what you have, so have I.
- My 4, 11, 3, 11, 12, 6, 4, often makes infants cry.
- My 9, 11, 10, 16, 5, are what a number play.
- My 10, 7, 8, 4, is dark and dismal, so they say.
- My 10, 11, 14, 8, 4, is the name of a State.
- My 9, 11, 1, 4, is where lovers often wait.
- My 9, 3, 11, 10, 10, 11, 3, is a useful book.
- My 10, 4, 11, 1, is what women often cook.
- My 3, 11, 7, 8, is what all nations need.
- My 5, 10, 11, 3, 1, is the name of a weed.
- My whole is what all farmers need,  
Without it they must work indeed.

A. B. S.

2. I am composed of 11 letters:

- My 7, 1, 4, 9, 11, is a level territory.
- My 1, 9, 11, 3, 6, 5, 11, is the name of one of the Presidents.
- My 7, 2, 10, 5, is a collection of water.
- My 7, 5, 4, 8, is a sketch of a piece of ground.
- My whole is a subject much agitated.

## A New Puzzle.

Whoever visited New York in February last must have met at every street corner men and boys doing a thriving business in selling a new game or toy known as; The "Sliding Number Puzzle." This game, which is for a single person, and therefore a *solitaire*, consists, as the engraving shows, of a box into which 16 small square blocks of wood fit quite closely. Upon the upper face of each block is a number, and these run from one to sixteen. When the puzzle is to be worked, one of the blocks is removed (the one having "16" upon it), and the others are placed face down upon the table, and mixed as in the stirring or "shuffling" of dominoes. The blocks being well mixed, are then placed in the box just as they are picked up, beginning at the upper left-hand corner, and filling to the right. When all the 15 blocks are in, there is a single space vacant, and this allows of a sliding of the blocks—one at a time, and of course through only one space. The trick, or puzzle, is to so move the blocks that they will be finally brought into the regular order of the numbers upon them—that is, block "1" is in the upper left-hand corner, "2" next at its right, and so on until "15" is reached at the end. So far as the explanation of the puzzle is concerned it is very simple, but to get the blocks into the regular order is quite another thing. Some persons, after having spent several hours, and even days, have been unable to get them right, while others have succeeded in doing it after a few minutes. Of the latter, it may be said it was all guess work, and the next time they try, it may take them a much longer time. The possible arrangement of blocks as they are placed hap-hazard in the box, are so numerous, that it is safe to say that they can never be twice alike; therefore the movements are different in every succeeding "game." It is interesting to see how much "taken" people have been with this puzzle, bankers and business men have stood in groups at the entrances of their places of business, and exercised their calculating powers over some hard move, or laughed to

THE SLIDING NUMBER PUZZLE.

see some one else move and move again, and not make the least particle of progress. The puzzle took with the boys at once, who freely invested their dimes and half dimes—the puzzles being of various sizes, shapes, and prices, to suit the demands of the trade. In our first trial of the puzzle we failed, but in a second attempt, about half an hour of "shoving around" brought all the blocks to their proper places. The boys and girls of the *American Agriculturist* family will be interested in this puzzle, we think, and as we understand it is not patented, any boy can make one for his own and other's amusement; the engraving will show how it is made.

## A Bed of Mixed Plants.

Misery is said to make strange bed fellows, but misery has nothing to do with bringing these plants together in the same bed, though they may be "strange," as some of the plants have probably never met each other before. In this respect there is a newness about our bed that may give it interest. There are no paths—no regular ways to go on our round of inspection—and therefore we are at liberty to "go as we please." As the plan of planting is not of the formal style, our ramble may also be irregular, and if the first plant that gains our attention is not in one of the four corners, it will make no difference.

No. 1. There is a little low plant that often covers the moist ground along the edges of woods, with its pale-green mottled leaves dotted with purple, and suggesting the tongue of some reptile, and one of the common names of the plant. From between the leaves the slender stalk runs up, and bears on its end a yellow lily-like flower, and of such size and weight as to cause it to hang its head as if in modesty. It generally figures largely in the bouquets which children bring in from the woods in early spring. We have never seen a dog try his teeth on this plant, the color of which is far from violet.—No. 2. This

is the representative of a *genus*, or little group of kinds of plants, ten of which are found in the Eastern U. S., some flowering as early as April, while others prefer the hot month of July for showing the regular pretty flowers which are sometimes quite showy because borne in large clusters. A tall kind is very generally found in old flower gardens growing in clusters, the stalks small and straight, ending in a large oval cluster of showy purple flowers. A low kind flowers early, and covers the ground with a mat of mossy pink, also common in cultivation.—No. 3 is a shrub that grows in large clumps in low places, the young shoots being highly prized for whips by boys, and in spring used for making whistles. The flowers are very small, but hang in long soft bunches, which, from their shape and feeling, might remind one of the bushy tail of a squirrel or a cat. The color is yellow, as also is the bark of the twigs, and the bees and other insects are very fond of the flowers, from which they gather much sweet. The plant would be a little out of place in a well kept flower garden.—No. 4. While we are in the low, moist ground, let us notice another and a very different plant, far more attractive from the strange form and coloring of its cluster of flowers than the flavor of its large turnip-like stem below ground. Those who have tasted of this plant seldom like to repeat the experiment. The leaves are usually two in number, and like those of the ordinary clover, composed of three parts, but very much larger. The hood-like richly colored covering to the fleshy flower cluster is very peculiar, and from the arrangement of floral parts the common name is derived.—No. 5 is a particular favorite in spring window gardening; growing from a bulb, and often put in tall and neat glass jars. When in bloom the large flower cluster makes up the principal part of the plant, the individual flowers may be of almost any shades of color, waxy in texture, and extremely fragrant.—No. 6. When children get together in the pasture or along the roadside they are quite sure to pick the bright yellow flowers of number 6 and place them under the chins of their companions to determine the fondness which the one examined has for a certain article of food. The juice of the plant is not agreeable to the taste.—No. 7, the botanists say, is a near relative of the last, though the leaves are of a different shape, and the flowers entirely different in outline, much more showy, each possessing five long tubes, in the bottom of which a little drop of honey is to

thus reach the nectar. This is one of the most showy of wild spring flowers, and is fond of growing on some be found—provided some busy bee has not made his early visit and extracted it. Bees are getting very wise, and some of them, instead of taking the trouble to crawl head first into the tube, just punch a hole near the bottom, and

A COLLECTION OF STRANGE LOOKING PLANTS.

rocky cliff just out of reach of those passing below. It is not of a nature to bind itself very closely to a column.—No. 8. A very delicate plant is often found in the woods in early spring, with slender branches and peculiar heart-shaped, scattered flowers. There are two broad sprigs to each flower, and as they hang and dangle on their slender supports, they may remind one of a garment hung up as a sign in front of a clothing house in Holland.—No. 9. Again we return to the plants of the lily tribe, and this time to one which frequents rich ground, as along low river banks, where it grows to some five feet in height. The flowers are small, but make up for their size in number. The stem grows from a creeping one beneath the soil, and as the stem above ground dies at the end of the year it leaves a scar, so that by digging up the stock the age of the plant in years can be determined by counting the scars. The mark or scar resembles the impression made by a stamp. Just why the common name of this plant should be associated with that of a very wise man of old is more than we can tell.—No. 10. Here is a pretty little plant, and one that is so small that we should overlook it were it not for the delicacy and beauty of its very early flowers, coming out so soon as the snows have cleared away from the margins of the woods. Small as it is, it is the welcome friend of every seeker of early gems.—No. 11 is one of the earliest of garden plants to send up its flower to cheer us, and is so near a relative of the *Daffodil* that we are not sure but they are almost twin sisters.—No. 12. This is not a handsome plant; it grows in damp places, and is quite common. The flowers are rather large, varying in color from white to purple. The mouth of each blossom is nearly closed, and from this, and the size and shape of the flower, it resembles quite strongly the head of some animal.—No. 13 takes its common name from the long, slender, yellow, bitter, fibrous roots which this plant has in great abundance. The leaves are evergreen and shiny. It is a bog plant, with small white flowers, which are not expected out until May.—No. 14. A standard garden plant, with pretty flowers of a characteristic shade, and the name of the plant is the accepted name for the shade of color which the flowers often possess.—No. 15 is not at all attractive, and we put it here as a sort of contrast to the showy plants which are in the bed around it. The common name is derived from the shape of the young pod, which in outline resembles that of the *head-dress*

THE OLD BIRD AND HER LITTLE ONES THAT LIVED IN A SHOE.

of a high officer in the church.—No. 16. The flower of this is bell-shaped; perhaps it is not worth while to speak further of this.—No. 17. Old neglected cultivated grounds and places in meadows and pastures not occupied with a turf generally abound in this plant, which grows into a bushy herb with a great abundance of small flowers produced through all the season. After the flower comes a pod of small size, the shape of which suggests a part of the name.—No. 18. When a name is so generally applied as to include a number of kinds of plants, it becomes difficult to describe it—but it is safe to say that it is a rough looking plant with a head of flowers on the same plan as the sunflower, only much smaller.—No. 19. The tone among the plants of the flower bed is closed with the notice of the most poetical member of the collection. Though small as a plant, its flowers are large and particularly striking in their appearance, suggesting the human face to those who are at all imaginative. It probably has more common names than any other flower, and one of these implies that it can bring quiet to an important organ of the human body.

### Birds and Nest Building.

The first fresh note of the earliest bird, as it comes to one's ears on the still morning air, is full of joy and gladness. After a long and cold winter, anything that tells us that spring is at hand, is very welcome. The spring birds mark a place on the memory of every farmer's child; and if I am not entirely mistaken, the farmer himself is touched and made glad by the sweetness and new life

which the returning songsters bring from their Southern winter homes. The Chickadees, Snow-birds, and a few others, remain with us through the winter, and all are thankful for their cheering presence; but it is only when the warm spring days fill the air with the voices of the new comers, that bird life is at its best. The twittering Swallows, the pretty Blue Birds, the sprightly Thrushes, the noisy Bobolinks, and the whole list, bring back the realities of a growing season. After the return, and the general, and generous serenade is over, the active duties of bird house-keeping are uppermost in the minds of the members of the feathered tribe, and in these, and the busy preparations for the same, the greatest charm of bird life consists. In nothing do birds show more tact, skill, forethought, intelligence, and all the other qualities which make them take such a rank, than in the building of their nests, and the rearing of their young. Each kind of bird has its own peculiar way of forming its nest, selecting those materials best adapted to its wants. The Eagle finds some crag, high up out of the reach of its foes, and then in the solitude of the upper air, builds its coarse nest of sticks and moss, and brings forth its well protected young. The little Humming-bird constructs her thimble-like nest, with the greatest nicety, using only the softest of materials; and with a nature very unlike that which we should look for in so small a creature, defends her home with a courage and success, that would put to shame many another two-legged animal, not graced with fine feathers, or fine feelings. The black, unmusical, hated, hunted bird, familiarly known as the Crow, loved by none, shot at by all who can get within its range, poi-

soned by many, and a great lover of early corn, does not build its nest upon the ground, or within the easy reach of man. The school boy who would rob Crows' nests, can spend much time in climbing large and lofty trees, and must possess a great degree of courage, to insure success. It is better for him to go after school if he goes at all, as he will then be sure of the day's schooling. If boys will confine their nest-robbing, and bird-hunting, to such kinds as the Crow, but very little harm will be done to our birds. To any who will put a cruel hand to the home of the many innocent and useful birds, I would suggest that they receive from their parents that impressive instruction that the meanness of their conduct demands. A bird in a boy's hand, is not worth two that are out of his reach. If children were not so inquisitive—did not have such a strong desire to see and know things—it might be, in some cases, all the more pleasant for the birds. This I know from my own experience. The innocent "ground birds," unsuspectingly find some place at the foot of a bush, or under the edge of a sod, and out of grass, hairs, feathers, thread, wool, cloth, etc., make a nest that the feet of passing cattle, or the hands of evil boys can quickly destroy. The Robin—a bird loved at all seasons, except when the cherries and other small fruits are ripe—builds its nest in a variety of situations. In my boyhood days, it seemed to have a peculiar liking for the corners of old rail fences, and very good places they were in more senses than one. I have watched the whole process of nest-building, from the simple mud foundation, up to the generous, and well-shaped completed home. Then climbing up, with the old bird dashing at my head, saw that there was one egg, then the two, the three, and finally the four—frequent calls being made just to see how everything was getting on. Twelve days later, the little robins broke the thin blue walls of their prison, and the light of a new world came into their inexperienced eyes. I confess to aiding them a little in this transformation scene, and to helping the mother bird feed these great-headed, big-mouthed, piping, hungry, homely, half-covered younglings, while the harassed mother cried (we

may suppose) in a loud voice; "These are my little ones: torment me no more." I have a weakness for nest building, and no longer ago than last spring, a pair of birds built a nest in a pear tree, but a few feet from one of my windows, and if the truth was told, some one kept well posted on the progress of the work; and for this the owners may have reason to be grateful, as one day a boy was found molesting their quiet reign, and the youth was soon led to see the error of his way—and that to his own home. Luckily the birds and nest were unharmed, and in due time a family was raised. One ambitious fledgling was saved from the "jaws of death" (cat), by human hands, and the wisdom of not leaving home too early in life, was impressed upon the other members of the household. The nest to-day is in the leafless branches of the tree, waiting, it may be, to be refitted in a few days, and occupied by its former owners.

The accompanying engraving shows hut one of the many ways in which old things are turned to good account, by the ingenuity of birds. An old shoe has made a most acceptable home for a little feathered family. Having served its day as a cover for some foot, it now becomes a protection to a number of little feet, along with the bodies attached to them. Unlike the old woman who dwelt in the same style of a home, the mother bird, with a goodly brood, seems to know what to do with her children. She may experience more trouble a little later in the season, when they become more independent, and are out from under her wings—When they get out of the shoe, I suppose they step in by the way of the *in-step*; of course, one can not be *shoe-r* of this. UNCLE HAL.

THIRTY-FIFTH ANNUAL REPORT

OF THE

New-York Life Insurance Company,

Office, Nos 346 & 348 Broadway.

JANUARY 1, 1880.

Amount of Net Cash Assets, Jan. 1, 1879, - - - - - \$36,213,457.61

Less deduction to cover decrease in value of U. S. Bonds and other assets..... \$135,966.93

\$36,077,490.68

REVENUE ACCOUNT.

Premiums..... \$6,382,875.25

Less deferred premiums January 1, 1879..... 379,839.09—\$6,003,036.16

Interest and rents..... 2,339,875.93

Less interest accrued January 1, 1879..... 376,225.93—\$2,033,650.00—\$8,036,686.16

\$44,114,176.84

DISBURSEMENT ACCOUNT.

Losses by death, including Reversionary additions to same..... \$1,569,854.22

Endowments matured and discounted, including Reversionary additions to same.... 1,015,256.22

Annuities, dividends and returned premiums on cancelled policies..... 2,236,379.97

Taxes and re-insurances..... 173,608.64

Commissions, brokerages, agency expenses, and physicians' fees..... 626,253.30

Office and law expenses, salaries, advertising, printing, etc..... 307,392.81—\$5,928,745.16

\$38,185,431.68

ASSETS.

Cash in bank, on hand, and in transit (since received)..... \$ 1,961,701.43

Invested in United States, New York City, and other stocks, (market value \$14,356,192.94)..... 13,544,671.96

Real estate..... 4,974,573.68

Bonds and mortgages, first lien on real estate (buildings thereon insured for \$14,287,000.00, and the policies assigned to the company as additional collateral security)..... 15,313,278.95

Temporary loans, (secured by stocks, market value \$1,300,000)..... 850,000.00

\*Loans on existing policies (the reserve held by the company on these policies amounts to \$3,160,000)..... 621,408.02

\*Quarterly and semi-annual premiums on existing policies, due subsequent to Jan. 1, 1880..... 367,969.02

\*Premiums on existing policies in course of transmission and collection (estimated reserve on these policies \$330,000; included in liabilities)..... 211,625.23

Agents' balances..... 22,199.23

Accrued interest on investments Jan. 1, 1880..... 317,989.11

\$38,185,431.68

*\*A detailed schedule of these items will accompany the usual annual report filed with the Insurance Department of the State of New York.*

Excess of market value of securities over cost..... 811,520.98

Cash Assets, Jan. 1, 1880 - - - - - \$38,996,952.66

Appropriated as follows:

Adjusted losses, due subsequent to Jan. 1, 1880..... \$225,662.64

Reported losses, awaiting proof, etc..... 213,271.31

Matured endowments, due and unpaid..... 32,780.98

Reserved for re-insurance on existing policies; participating insurance at four per cent Carlisle net premium; non-participating at five per cent Carlisle net premium..... 34,016,840.82

Reserved for contingent liabilities to Tontine Dividend Fund, over and above a four per cent reserve on existing policies of that class..... 1,371,482.18

Reserved for premiums paid in advance..... 16,543.25—\$35,876,581.18

Divisible Surplus at four per cent..... 3,120,371.48

\$38,996,952.66

Surplus, estimated by the New York State Standard at 4 1-2 per cent, over.....\$7,000,000.00

From the undivided surplus of \$3,120,371.48, the Board of Trustees has declared a Reversionary Dividend to participating policies in proportion to their contribution to surplus, available on settlement of next annual premium.

DURING THE YEAR, 5,524 POLICIES HAVE BEEN ISSUED, INSURING \$17,098,173.

H.W. JOHNS'  
ASBESTOS  
Liquid Paints.

ARE STRICTLY FIRST-CLASS PURE  
LINSEED OIL PAINTS.

THE BEST IS THE CHEAPEST.

These are the purest, finest, richest and most durable  
paints ever made for structural purpose. They are prepared  
ready for the brush in sixteen newest shades and standard  
colors, suitable for the tasteful decoration of dwellings and  
all classes of buildings, inside and out, and for all purposes  
where a perfect protective coating is required, and, covering  
body and durability considered, they are twenty-five per  
cent cheaper than the best White Lead or any other kind  
of paint now in use.

Our Asbestos Liquid White has been adopted for inter-  
rior and exterior work of the U. S. Capitol at Washing-  
ton.

The Metropolitan Elevated R. R., of New York City,  
is painted with our paints.

ASBESTOS ROOF PAINT.—Brown, Red, Yellow,  
Gray, Slate, and Cream, for tin and shingle roofs, iron work,  
agricultural implements, fences, out-buildings, etc. We

Alice Burpee & Co., 221 Church St., Philada., Pa.

## RAFFIA FIBRE.

## A NEW BAST.

Superior every way to all other known articles for binding in PLANTS and similar work. Especially distinguished for its Lightness, Pliability, and Durability, its Freedom from Rot, and Great Divisibility into the smallest fibres.

Can be used WET or DRY. It is by far the most economical tying Bast, and now in great demand in Europe.

Orders received, and small samples with prices furnished by Mr. THEODORE SCHUSTER, 419 Hickney Street, Brooklyn, N. Y.

**J. W. WUNDERLICH, Frankfort (on the Main), Germany.**

## Three New Potatoes.

**1. Pride of America.**—In appearance resembles the Snowflake, a few days later. Very productive, large size, an excellent keeper, of superior quality.

**2. Matchless.**—Tubers very handsome, round; pale-red; flesh fine grained, pure white, and of excellent quality. A great cropper, an excellent keeper.

**3. Silver Skin.**—A cross between the Early Rose and White Peach Blow. Tubers medium to large. Skin smooth, silvery white, russeted. Flesh snowy white, fine grain, splendid quality, an excellent keeper.

Prices of each of the above, \$1.00 per lb., 3 lbs. \$2.50, by mail, prepaid. By freight or express at purchaser's expense, 1/2 Peck, \$3.00; 1 Peck, \$5.00; 1/2 Bushel, \$7.00; Bushel, \$12.00; Barrel, \$25.00.

All the older standard varieties at market prices. Bliss' Illustrated Potato Catalogue, contains a descriptive list of all the new varieties recently introduced, with many other desirable sorts, beautifully illustrated. Centennial collection of 500 varieties. Also much useful information upon the cultivation of this valuable esculent. 10c.

## RELIABLE ONION SEEDS.

Our stock of Onion Seed has been raised from selected bulbs, and carefully tested, and we can recommend it with the greatest confidence, as equal to any ever offered in this or any other market.

	oz.	1/2 lb.	1 lb.
Extra Early Red.....	\$0.35	1.10	3.50
Early Red.....	30	1.00	3.00
Wethersfield Large Red.....	25	75	2.00
Danvers Yellow.....	40	1.25	4.00
Yellow Dutch.....	30	1.00	2.50
White Portugal.....	30	1.00	2.75
Early Cracker.....	40	1.25	4.00

Southport White Globe.....	35	1.10	3.50

In lots of 5 lbs. and over, 50 cents per lb. may be deducted. Postage must be added at the rate of 16 cents per pound when ordered by mail.

## Prickly Comfrey Roots.

25 ets. 1/2 lb., 75 ets. 1 lb., by mail, post-paid, by express 50 ets. 1 lb., 5 lbs. \$2. Directions for cultivation accompanying each lot.

## FRESH, PURE SEED

Our New England-grown Seeds have secured an enviable reputation, and we again invite the attention of Farmers, Gardeners, Florists, and others to our new and select stock of every variety, which we offer at low prices. Our Boston Market Vegetable Seeds have a special reputation for excellence, and our stock of Flower Seeds is unsurpassed in all the choicest varieties. Seeds sent by mail to all parts of the country, and guaranteed to reach purchasers. New Catalogue for 1880 sent free.

**HOVEY & CO., BOSTON, MASS.**

My Annual Catalogue of Vegetable and Flower Seed for 1880 will be ready by January, and sent free to all who apply. I would invite attention to the superior character of the vegetable engravings, most of which were made from photographs of vegetables grown on my seed farms. I offer one of the largest collections of vegetable seed ever sent out by any seed-house in America, a large portion of which were grown on my six seed farms. All seed sold from my establishment warranted to be both fresh and true to name; so far that should it prove otherwise, I will refill the order gratis. As the original introducer of the Hubbard and Marbled Squashes, the Marbled Cabbages, and a score of other new vegetables, I invite the patronage of all who are anxious to have their seed directly from the grower fresh, true, and of the very best strain. **NEW VEGETABLES A SPECIALTY.**

**JAMES J. H. GREGORY, Marblehead, Mass.**

**WHITE WATER LILY.**—Strong roots of this fragrant Lily, with printed directions for planting in tubs and ponds, 25 ets. each, \$2 per doz., by mail. **MANN BROS., Randolph, Mass. P. O. Box 162.**

## NEW POTATO, "ST. PATRICK."

In appearance the St. Patrick is undoubtedly one of the handsomest Potatoes ever grown; it has a smooth, white skin, and white flesh, few and shallow eyes; in shape it is rather oblong than round, and has no core or hollow; it is also a strong and hardy grower, and, from all accounts, has withstood the rot so prevalent last season better than any other sort. It produces but few small tubers, ripens medium early, and, finally, it is enormously productive and of fine quality.

At the Fall Exhibition of the New York Horticultural Society, held in this city, September, 1879, the St. Patrick shown by us was awarded the First Premium over all other Seedling Potatoes exhibited.

Price 50 cts. per lb., by Mail.  
 Or by Express or Freight, \$2.50 per peck; \$3.00 per bushel; \$30.00 per bbl.

We also offer selected stocks of the following leading Seeds:

BEST.	—Early Blood Turnip.....	1 lb.	1 lb.
	—Dark Red Egyptian.....	\$0.10	\$0.35
ONION.	—Early Flat Red.....	0.20	0.75
	—Wethersfield Red.....	0.75	2.75
	—Yellow Danvers.....	0.50	2.00
	—Yellow Dutch.....	1.00	3.50
RADISH.	—Round Dark Red.....	0.25	0.75
SPINACH.	—New Savoy Leaved.....	0.15	0.40

If by mail, postage must be added at the rate of 16c. per lb. Catalogue for 1880, free on application.

**PETER HENDERSON & CO.**  
 35 CORTLANDT ST., NEW YORK.

## NEW SEED WAREHOUSE.

THE FIRST TO INTRODUCE EUROPEAN PRICES, allowing purchasers to make their own selection of Flower and Vegetable Seeds in packets, at the extraordinary discount of 33 1/2 per cent. from Catalogue rates. CATALOGUES SENT FREE TO ALL.

## DESIRABLE NOVELTIES.

**Early Washington Tomato.**—A very handsome variety, of perfect form, smooth as an egg, and rich, deep red color. Fully a week earlier than "Acme," as solid as "Trophy," and decidedly superior in flavor. Per packet, 15 cts.

**Carrara Rock Cauliflower.**—The earliest variety known; produces beautiful, compact, snow-white heads of the finest quality. Resisting heat and drought, it will head where other varieties fail. Per packet, 50 cents; half oz., \$6.00; oz., \$10.00.

**Coral Flesh Musk-Melon.**—(From Japan.) A very early, densely netted variety, of round form and medium size. The rind is remarkably thin, while the succulent coral flesh is thick, deliciously crisp and melting. Per packet, 15 cts.

**A. D. COWAN & CO.,**  
**AMERICAN SEED WAREHOUSE,**  
 114 Chambers Street, New York.

offered Tools so well made, beautifully finished, and perfect in practice.

combined so well, variety of work with ease of operation. These machines quickly save first cost. They are prominent *Agriculturist* Premiums, and Jas. Vick says he has never sold any so popular. Correspondence is solicited, and Descriptive Catalogues with engravings are sent FREE.

## THE FIRE-FLY GARDEN HOE AND PLOW

Makes the Care of a Vegetable Garden a Pleasure.

10,000 families who could not find time to keep a vegetable garden, if attempting its cultivation with the ordinary hand hoe, can raise their own vegetables successfully and profitably, by the use of one of these labor and time-saving tools. Mold-board, tempered and polished steel. Circulars free. Price \$4.00.

S. L. ALLEN & CO., 229 Market St., Phila., Pa., Man'rs Planet Jr. Goods.

# THE MONITOR SEED DRILL.

This is the most complete and positive Seed Drill ever invented. It is radically different from and superior to all others. It is the only machine which measures and drops the seed with a positive motion, and exactly the same amount at each foot or yard. It has been tested by 6 years' use in Massachusetts, and was awarded the highest prize at the "Centennial." The "MONITOR" has been thoroughly tested during the seasons of 1878 and 1879, and heartily endorsed as a

# POTATO BUG. COTTON WORM. CANKER WORM.

THE BEST INSECTICIDE EVER USED.

# London Purple.

(Trade Mark.)

Sold by all Wholesale Druggists and Stores throughout the United States. It not obtainable of nearest dealer, send direct to sole manufacturers, HEMINGWAY'S LONDON PURPLE COMPANY (Limited), 60 Mark Lane, London, England.

A. R. WHITEY, Franklin Grove Orchard and Nurseries, Lee Co., Ill., writes: "We have bid the Canker Worm a long farewell, and have done it with your LONDON PURPLE. We put in about three-fourths to one pound of LONDON PURPLE to 44 gallons of water, and applied with a force pump. It is better than Paris Green, as the particles of LONDON PURPLE adhere to the leaves and Paris Green does not."

## PEARCE'S IMPROVED Cahoon Broadcast Seed Sower.

For Sowing all kinds of Grain and Grass Seed.

Does as much work as 5 men can do by hand, and BETTER work than can be done by any other means whatever. Agents wanted in every county in the United States. Price \$6. Send stamp for circular.

## HAWORTH'S WIRE CHECK ROWER.

Acknowledged by all farmers to be THE BEST AND ONLY PERFECTLY SUCCESSFUL Wire Check Rower. Will plant FIVE ACRES more a day than any other, as the Wire is not removed from the machine in planting the entire field. Eleven years' use has demonstrated the fact that the only successful way to use a rope or wire line is for the machine to transfer it into position to plant the next row. Do not buy a Wire Check Rower unless the line crosses the machine, as it will last twice as long as a wire run on one side, which must be dragged into position regardless of obstructions met as the planter crosses the field, and which causes friction, inaccurate checking, and breaking of the wire. In our Check Rower the elasticity of the wire and its large curve in passing over the machine, prevents a particle of bending or displacement in the wire, such as occurs in Check Rowers where the line is dragged into the pulley at an angle and high tension, and both bent and displaced as it enters the pulley. Dragging the line into position also causes canting, or lopping, of the planter, by which one row is planted too deep and the other too shallow. Our ROPE CHECK ROWERS are too well and favorably known to call for any extended notice. For full description of our WIRE CHECK ROWER and the three styles of ROPE CHECK ROWERS which we manufacture, write for a circular. HAWORTH & SONS, Decatur, Ill.

## Hardy Perennial Plants

Are increasing in popularity, because they are Hardy, their roots living through the winter—and Perennial, appearing year after year in the same place. They include the most beautiful kinds that bloom all through the season, from earliest spring to latest fall. Send for free descriptive Catalogue of the largest collection in the country—including Hardy Climbers, Flowering Shrubs, Lillies, Phloxes, Ferns, etc. Also choice native plants. WOOLSON & CO., Box 180, Passaic, N. J.

Illustrated catalogue sent free on application. **W. V. SKED & CO., Successors to SKED, PADDOCK & Co., Cleveland, O.**

containing a great variety of Items, including many good hints and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Continued from Page 133.

In justice to the majority of our subscribers, who have been readers for many years, articles and illustrations are seldom repeated, as those who desire information on a particular subject can cheaply obtain one or more of the back numbers containing what is wanted.

Back numbers of the "American Agriculturist," containing articles referred to in the "Basket" or elsewhere, can always be supplied and sent post-paid for 15 cts. each, or \$1.50 per volume.

**The German Edition.**—All the principal articles and engravings that appear in the *American Agriculturist* are reproduced in the German Edition. Besides these, there is a special department, edited by an eminent German cultivator. Our friends can do us a good service by calling the attention of their German neighbors and friends to the fact that they can have the paper in their own language, and those who employ Germans will find this Journal a most useful and acceptable present.

**Bound Copies** of volume 38, and of every previous volume back to Vol. XVI. (1857), neatly bound, with gilt backs, Index, etc., are supplied at \$2 each (or \$2.30 if to be sent by mail). See Publishers' Notes, 2d cover page.

**Clubs** can at any time be increased by remitting for each addition, the price paid by the original members; or a small club may be made a larger one at reduced rates, thus: One having sent 6 subscribers and \$7, may afterwards send 4 names more and \$3, making 10 subscribers for \$10.00; and so for the various other club rates.

**Terms to New South Wales, New Zealand, Australia, Africa, etc.**—To several Inquirers. Under the latest revision of the Postal Union Regulations the price of the *American Agriculturist* (either English or German edition), including postage prepaid through, will be covered by 7 shillings sterling per annum. This applies to the above countries, and to all others embraced in the General Postal Union. The simplest mode of remittance is by Postal Money Orders, payable in London, to the order of Orange Judd Company. These can be readily cashed in N. Y. City at a slight discount, which the publishers will cheerfully pay. For Club rates, (postage included), see our second cover page, and reckon 22 cents to the shilling sterling.

**Some Fish Hooks.**—It is reported that a single factory at New Haven, Conn., made 23,000,000 fish hooks during last year. If these averaged 1½ inch each, and were laid down end to end, they would extend 544 miles, or about from Washington to Boston. If only an inch long, they would extend 363 miles, or just the length of the Erie Canal from Albany to Buffalo.

**The Western National Fair Association.**—The first show bill announcement for a fair for the coming autumn, is from the enterprising State of Kansas. It is of a new organization with the title of "The Western National Fair Association," and is to hold its first exhibition at Bismark Grove, near Lawrence, Sept. 13-19. Over \$30,000 in premiums are offered, and the largest agricultural and industrial display ever made beyond the Mississippi is anticipated.

**Old Fruit Cans.**—If we should bring together and present in one article, all the various devices for utilizing old fruit cans, that we have published in the last 20 years, it would be a curious array. Every now and then a new method is added to make these cast off affairs of service. The latest comes from Baltimore. A friend there draws upon them for a supply of tin. By heating sufficiently to melt the solder, the tops and bottoms come off, the joint at the side opens, and the pieces that formed the body of the can are flattened out, and kept in stock. Is a patch needed under a shingle, does a knot hole or a rat ditch need to be stopped; does the horse gnaw the wood-work of the stable? A piece of tin is the remedy.

**"Spring Poor."**—No animal should be permitted to fall off in flesh during the winter from lack of food and care. Especially important is it that the horses—upon which the spring work falls so heavily—should be in good trim when the spring opens; in good flesh, good health, and of course, as a consequence, in good spirits.

## Catalogues Received.

Catalogues are many—space is narrow. Our friends must be content with the briefest acknowledgement.

## SEEDSMEN.

R. H. ALLEN & Co., 189 and 191 Water Street, N. Y. Neat and full. Grass and Farm Seeds a specialty.  
J. H. ANDRE, Bingham's, Tioga Co., N. Y. A special Potato catalogue.

## DAIRY APPLIANCES.

CORNISH & CURTIS, Fort Atkinson, Wis.—Rectangular Churn and Lever Butter Worker.

MOSELEY & STODDARD, Poultney, Vt. Moseley's Cabinet Creamery.

C. H. R. TRIEBELS, Philadelphia, Pa. The Lilly Butter Worker.

## DEALERS IN FERTILIZERS.

BOWKER FERTILIZER Co., Boston, New York, and Rochester. The Stockbridge and other manures, with directions for their use.

H. B. GRIFFIN, No. 70 Cortlandt Street, N. Y. Peruvian Guano, Phosphates, and Fertilizers generally.

MANHATTAN FERTILIZER Co., 38 Platt Street, N. Y. Blood Guano, Ground Bone, and Chemicals.

MAPES' FORMULA AND PERUVIAN GUANO Co., 158 Front Street. Mapes' Complete Manures, Peruvian Guano, etc.

A. H. WARD, Bridgewater, Mass. Agricultural Chemicals and Special Fertilizers.

**The Mapes Complete Manures.**—Those interested in the question of fertilizers, will find this pamphlet instructive reading. In the Reports of the *American Agriculturist* Fertilizer Experiments, the number of crops to which chemical fertilizers were applied, is limited, while the pamphlet in question gives the result of their application to almost every crop grown in our climate. The results with Cauliflower, Onions, and other "truck" crops, show that stable-manure is not the only fertilizer that can be profitably used upon them. There is no secrecy about the composition of these fertilizers; if there were, we should say nothing about them.

**Life Insurance A Duty.**—Every man has or ought to have some care or pecuniary responsibility for others resting upon him—for wife, or children, or friends, or for some public enterprise. And no man can drop off suddenly by death, as every one is surely liable to do, without danger that his family, or perhaps his creditors would be embarrassed, unless he be one of the few who have ample supplies of registered government bonds to more than offset all possible contingencies of fire and flood, of financial panics, or the failure of others. Wide extended observation and carefully prepared statistics show with almost absolute certainty how many persons out of every ten thousand will die annually. It is a very easy matter, therefore, for a company of persons to unite, and by mutual contribution to a common fund provide for the bestowal of a given sum to the family or creditors of each one who shall drop out by death during any year. Take the figures on page 155 in illustration. We there find 45,715 persons contributing an average of \$140 a year, which, with the interest from the already accumulated great fund of nearly 40 million dollars, is sufficient to secure to each person who dies an average of \$3,000, and except in very rare years of extraordinary mortality, there is a large surplus to be divided among the contributors, or to be deducted from their next year's payments. A man of 30, having a wife or children, or aged relatives, or creditors depending on him, can have in store for them \$1,000 for each \$32.00 he annually contributes to the general fund, less his share of the dividends. The fact that he has this provision made will often be a strong

help to his recovery from illness, by lessening his anxiety and worry about those he may leave behind him. Those not already fully insured should write to one or more of the large and well managed Companies like the N. Y. Life, whose Reports appear from time to time in our columns, and get and study their tables, explanations, etc., which are furnished gratuitously to those desiring them.

**London Purple.**—If we mistake not, the *American Agriculturist* was the first to call attention to London Purple, as a substitute for Paris Green, as an insecticide. Last season's experience of a large number of prominent cultivators, is now made known, and more than sustains all that was claimed for it, not only in destroying the "Potato Bug," but in depriving the Canker Worm of its power of destruction. The testimony of Prof. Riley as to its power of destroying the Cotton Worm, is most important; during his investigations in the cotton-fields last summer, London Purple was thoroughly tested in Georgia, Alabama, and Texas, and was found to kill the Cotton Worms, without injury to the plant. Prof. R. advises using it with water, mixing half a pound with 50 to 55 gallons of water. Being a "by product," that is obtained incidentally in the process of making Aniline dyes, it can be sold more cheaply than Paris Green, which must be manufactured directly. There is no temptation to adulterate the Purple, while the Paris Green, as ordinarily sold in country stores, is rarely pure. It should be remembered that the Purple being a compound of Arsenic, is equally poisonous, and is to be preserved and used with all the care advised for Paris Green.

**"New and Rare Plants."**—The Parsons Sons Co., Flushing, (L. I.) N. Y., issue a special catalogue with this title, and the contents certainly warrant it. We doubt if any establishment in Europe can show such a list of rare Japanese and other trees, shrubs, climbers, etc., both evergreen, and deciduous; several Horse Chestnuts, Maples, Oaks, Hydrangeas, Ashes, Magnolias, and others, quite new to cultivation, help make up a catalogue full of interest to every lover of choice plants.

**Tying Material—Raffia.**—For a long time Bass or Bast bark, was the universal tying material with gardeners and nurserymen. Large quantities of this are imported in the form of Russia or Archangel mats, which are used for packing furniture or similar articles, and are pulled apart by gardeners and others for the strands of which they are woven. Several years ago war shut off the importations of mats, and our nurserymen learned that they could prepare a better material from our native Linden or Bass-wood Tree. Cuba Bass, the inner bark of a tree of the Mallow Family, was introduced into England and to this country as a substitute for the Russian, and while it is very strong, it lacks the pliancy needed for most purposes. Lately there has been introduced from the East Indies, a material that appears to have all the good qualities of Bass without the faults of its substitutes. This is offered in our advertising columns as "Raffia," or "Raffia Fibre." It is in lengths of about 5 feet, and is about half an inch wide, but tapering gradually at one end. We take this to be derived from the stem of a species of *Cyperus* closely related to the Papyrus plant, and the same material as that from which the much esteemed India mats are made. The Raffia splits into the smallest fibres; it unites great strength with a silky softness and pliability, and for budding seems to be a most perfect tying material. How it will work in the rapid wholesale operations of the professional peach-budders, can only be told by experience.

**Dentaphone and Audiphone,** are names of new devices for utilizing the well-known fact that the bones, etc., of the head, can convey vibrations to the auditory nerve, and produce the sense of hearing. To many totally deaf persons these affairs are a new revelation, while those partially deaf often find great assistance from them. But those persons, in whom essential portions of the ear have been destroyed, or in whom they have been lacking from birth, are beyond the aid of these or any other appliances whatever.

**The American Veterinary College.**—The commencement of this excellent institution was held on February 27th last, in the presence of an audience noted for the large number of prominent scientists, merchants, and others. The graduates were 13, and represented six different States, with one from Bermuda. The customary addresses were made and prizes distributed. The occasion must have been a gratifying one to the officers and faculty of the College, and especially so to Dr. A. Liantard, its President, whose efforts in behalf of veterinary science, continued in spite of all obstacles, are now meeting deserved success. Young men who contemplate entering the medical profession will do well to consider if Veterinary Surgery does not present quite as useful a career as any other, and one more likely to be profitable.

**"The Botanical Gazette."**—This journal commenced its 5th volume with the present year. From small beginnings it has gone on improving and is now just such a medium as working botanists need for communicating with one another and with the world in general. The Messrs. Coulter deserve much credit for their efforts, and all botanists should aid them in what always must be a labor of love, by sending the price of subscription (\$1) to J. M. Coulter, Crawfordsville, Ind.

**Michigan Pomological Society.**—The Report of the Secretary of this flourishing Society for 1879 comes to us full of valuable information; and especially rich in its "Portfolio" items, which the Secretary, Mr. C. W. Garfield, has selected with great care. Michigan is a good fruit State, and its Pomological Society is doing good work, as shown by the high character of its reports.

**Butter Coloring** is so generally used in winter, that it becomes a matter of importance to have one that, while it gives a satisfactory color, shall be free from all unpleasant odor and taste, and especially from anything unwholesome. Abundant testimony is given that the Perfected Butter Color of Wells, Richardson & Co. meets these requirements, not only by American dairymen, but in England and other parts of Europe it has met with great success and approbation.

**The Robbins Family Washer.**—We gave last year our opinion in full as to this Washer and the principle upon which it works, which could not have been seen by our newer readers, and those sending us numerous letters of inquiry. We can not find time to write to each one of these in detail, and we must make this general reply serve for many. The Washer acts upon the principle of the "bucking tub," so generally in use in bleacheries, etc., where immense quantities of fabric are to be cleansed, and causes a continuous stream of boiling suds to fall upon, and pass through, the clothes. If the suds is clean it will make clean clothes. If already charged with the soiling material from very dirty clothes, it will not make but slightly soiled ones cleaner. Used with common sense and judgment, it can be a great help in washing. Left to those who have neither sense nor judgment, and who have a natural prejudice against whatever is different from that to which they have heretofore been used, such people will contrive to make it a failure.

**Draining, and the Reasons Why.**—Sometimes a catalogue or price-list is much more than it pretends to be. An instance of this is presented in a price-list of only four pages, by Wm. M. Bell, Smyrna, Del. The description of the tiles made and the prices at which they are sold occupy but a small space, while the rest is occupied by a condensed, well put treatise showing why people should drain, and telling how it should be done—whether to increase the crops of the farm or to promote the health of the family of the farmer.

**A New Work on Peach Culture.**—Mr. John Rutter, a skilled Nurseryman and Fruit Grower, of West Chester, Pa., has just published a small work on the Culture and Diseases of the Peach. The Author claims that peaches may be successfully and profitably grown, outside of the few localities heretofore regarded as especially "Peach Districts," and that the failures from "Yellows," and other diseases, are due to bad culture, or rather want of culture. He gives in a plain and unassuming style, the methods that he has found so successful himself, that he commends them to others. We trust that the work may be the means of greatly extending the culture of this favorite fruit.

**"Forty Years' Experience in Pear Growing,"** by William Parry, of Cinnaminson, N. J., is the title of a pamphlet of 20 pages, mainly filled by an address given by Mr. Parry, before the N. J. Horticultural Society. Much space is given to the Kieffer, and other new pears that are regarded as hybrids, between the Chinese Sand Pear, and our cultivated varieties, and of which Mr. Parry has strong hopes. The Author presents an excellent portrait of himself with the work, which will cause people to think that he must have begun pear culture at a very early age, in order to have gained 40 years of experience.

**A Slight Omission,** but an important one. Some one writes to inquire if a certain paper has stopped, as he can get no answer to the letters he has written to the office. If the letters sent to the other paper were like the one to us, it would be rather difficult for him to get an answer, as he gives neither town, city, or State.

**Just How.**—A correspondent wishes to know if we can not give an article that will tell him "just how" to prune his grape-vine. We could not do this without an exact diagram of the vine as it now is, and such directions for pruning this would be of no use as a guide for any other vine or for the same vine next year. The

growth of the vine is according to a few simple laws, and one to prune a vine properly, must, in the first place, have a definite idea of what he wants to do with it; then keeping in mind the manner in which he can do it in accordance with the laws governing the growth. There is no way of removing the necessity for thinking.

**"The American Entomologist."**—When Prof. C. V. Riley, nine years ago, found it necessary to suspend for a while the publication of this Journal, the fact was regretted by all interested in Entomology, whether in its scientific aspects or in its relation to Agriculture and Horticulture. That its publication, after an unexpectedly long interim, has been resumed, will equally interest the same persons we may feel sure, but the appearance of the Journal should be welcomed by that large number who, during its suspension, have become interested in Entomology as a science or as an important part of a cultivator's knowledge. The Journal re-appears with its former mechanical form. Its editorial force has been strengthened by the addition of Mr. A. S. Fuller, who brings valuable aid to Prof. Riley. The Journal promises to be, as it formerly was, not merely the organ of scientific entomologists, but one which the fruit-grower and cultivator generally can not well do without. The same prominence, as before, is given to the practical aspect of the science, and the Journal is one worthy of abundant support. This time the Journal is published in N. Y. City by the "Hub Publishing Company," No. 323 Pearl St., to whom subscriptions (\$2.00 per annum) may be sent.

**Peanuts in California,** are chiefly grown in eleven counties. The total number of acres is 436, with a yield of a trifle over a thousand pounds per acre.

**Weaning Calves.**—"L. E. B." The method of weaning calves by means of an artificial teat in the bottom of a pail, is very simple. All that is needed is to make a mold of elder wood, and cover it with soft leather or rubber tubing, and fasten this to the bottom of a pail. A sufficient opening must be made in the bottom of the tube to let in the milk, when the calf sucks the upper part.

**Farm Wages.**—The official reports show that with few exceptions the price paid for farm labor in the various States of the Union was 3 to 15 per cent lower during 1879 than the previous year. In New England, for example, the average rate was \$20.31 against \$22.60 for 1878. The decline in the cost of living has been in about the same ratio. In Minnesota, California, and other States and Territories in the Northwest, wages have been an exception to the rule throughout the East. As the wages have increased in the Pacific States, so has the cost of living in a much greater ratio. The English agricultural laborer receives on an average \$15.60 per month and that without board and lodging. In Ireland, Italy, Spain, and France, it is 5 to 12 per cent less than in England. In view of this the American farm laborer getting \$1 and board for eight months, and in many cases for the whole year, is doing well.

**A Modern State Fair: Graphic Description.**—Gov. Furnas, of Nebraska, must have been traveling eastward, for it seems hardly credible that his graphic picture, and unfortunately a too true one of some cases, could have been inspired by anything that would be allowed by the good people of Nebraska.... "Bands of Music, Dance Halls, Horse-races, Mule-races, Slow-races, Foot-races, Sack-races, Balloon Ascensions, Greased Pigs, Greased Poles, Wheels of Fortune, Rocking Swings, Tight-rope Performances, Female Pedestrians, all manner of Venders, from the Peanut Stands, *ad infinitum*, together with numberless nameless incidents, *et hoc genus omne*—all securing a crowd, good times, large gate receipts, and enabling the Board to 'pay out.'"

**Carp Culture in California.**—A correspondent of the "Pacific Rural Press," gives his experience in the culture of the carp, which, to say the least, is very satisfactory to him, and encouraging to all who may desire to grow this kind of food. In January, 1876, he bought six carp, one of which soon died. The first year he raised 2,044, and in 1877, 2,672, from the same five fish. In 1878, he disposed of two of the old fish and reared 4,000 from the remaining three. The crop for 1879 has not yet been put into figures. The four fish ponds cost \$50 each; first cost of fish \$30; food \$10; total, \$240. He has sold \$415 worth of fish, and has from 6,000 to 8,000 carp in his ponds, besides his family has been eating carp for the past 18 months. The ground devoted to this industry, that is, the area covered by the ponds, etc., is about a half acre; and it is to be remembered that it was wet, waste, and otherwise comparatively worthless land at that.

**Peaches for New England.**—We are glad to hear of the planting of peach orchards in places where their culture was long ago abandoned; in Eastern New York and Northern New Jersey peach culture has

taken a new start, and recently several inquiries come from New England. One obstacle to peach culture is the common notion that a peach tree should last an ordinary life time. In some peach districts they are content if they get two good crops in five years. Trees are exceedingly cheap, and when one planting shows signs of failing, set out another. Our New England correspondent asks for a list of about six varieties suited for market for Eastern Massachusetts. As to varieties nearly every place has one or more local varieties that succeed better than almost any others. For early varieties, Hale's Early, in many places rots so badly just at ripening, as to be useless. Waterloo, Amsden, and a number of other new very early kinds are offered, and seem worthy of trial. One planting for market should look into the merits of these. For six established varieties: Early York, Crawford's Early, Cooledge's Favorite, Old Mixon Freestone, Crawford's Late, Ward's Late Free; also Morris' White.

**Sale of Stock by Weight.**—Dr. J. B. Lawes, in a recent number of the "Mark Lane Express" stands up strongly in favor of using the scales in all sales of live stock. There is enough uncertainty in the farmer's occupation which cannot be avoided; but the guess-work and the great amount of time spent in making rough estimates, should be superseded by the quick and satisfactory method of actual weighing.

**Experience with Canada Thistles.**—F. Bacon writes from Lake Co., Ill., essentially as follows: "Eleven years ago I bought my present farm, and upon it was a patch of Canada Thistles covering about 1½ acre of land, bordering on a slough. It was so boggy and rough that it was impossible to mow them, even with a scythe, so they had yearly to be cut with hoe or spade, making the job an expensive one. Having the slough first well drained, I plowed the piece—through the summer of 1878—plowed, harrowed, or cultivated, every time a green plant appeared. On the first part of Sept. I gave the field a thorough plowing, harrowing, and rolling, and sowed broadcast, by hand, 2½ bushels of winter wheat. Having just threshed, I give the result, which was 81 bushels machine measure, weighing 66 lbs. to the bushel. I had one load of rakings that was threshed with spring wheat, that I have no doubt would have made 5 to 8 bushels more. Every part of it was lodged, and consequently there was a great deal left on the ground. I have no doubt that there were 100 bushels grown on the ground, and not a thistle has been seen since." But was this really the "Canada Thistle?" The ease with which it was subdued makes us suspect that it may have been some other thistle.

**Shrinkage in Hogs.**—A western farmer, to determine the amount of loss of weight in killing and dressing hogs, selected twenty hogs that had been fed in the average way, on corn, etc., and weighing about 150 pounds. The shrinkage in this experiment was a trifle over one-seventh of the live weight. The loss from the flow of blood in "sticking" was determined in two cases, namely, 8 and 7½ pounds. But the breed has much to do with all this, and such statistics, to be of value, should state the breed of the animals.

**A Wood Shed** is a necessary part of every economical farmer's home. It does not cost much in its construction; is a great convenience in keeping the wood dry, and furnishes a shelter in which much, if not all the work, of preparing the wood for the stove can be done in stormy weather in winter and the rainy days of summer.

**Cure for Cribber.**—"H. J. S., "Fisher's Ferry, Pa. The most effective remedy for a cribber, is to cause the horse to wear the cribbing muzzle, described in the *American Agriculturist* for July, 1875. This does not prevent eating or drinking, but the horse cannot take hold of his crib, or a post, with his teeth.

**North Carolina.**—We have on a former occasion commended the enterprise of Mr. Geo. Allen, Seedsman, of Newbern, in distributing the *American Agriculturist*, and in otherwise aiding the farmers of his State. He now publishes a bulletin, in which he gives "Fifteen Reasons for Emigrating to North Carolina," and other useful items.

**To Raise a Roof.**—"R. M. C., "Washington, Pa. It is an easy matter to raise the roof of a building so as to build an extra wall under it. Loosen the plates from the wall and raise the roof, one corner at a time, resting the roof on timbers placed across the corners of the building. As the roof is raised build up the wall, and as this is done, raise the roof. If the building is a frame one, the roof must be raised the intended height first, resting on blocks placed on the floor under it; and the studding spliced and mortised into the plate. The raising may be done by levers, a little at a time, or by jackscrews. But it should be secured as it is carried up, so that it cannot go over sideways.

## WILBER'S DIRECT DRAFT EUREKA MOWER

Is the LARGEST, CHEAPEST, and  
Lightest Draft Mower in the World.  
It lessens the expense of gathering the Hay Crop fully  
twenty-five per cent. Address  
**EUREKA MOWER COMPANY,**  
Towanda, Bradford Co., Pa.

## Union Railway Horse Power.

**THRESHERS AND  
SEPARATORS.**  
These Powers are  
**GUARANTEED**  
to produce more Power  
with  
**LESS ELEVATION**  
than any other Railway  
Power. Send for descriptive  
catalogue. **W. M. L.  
BOYER & BRO.,** 2101 Ger-  
mantown Ave., Phila., Pa.  
Also, manufacturers of the PREMIUM FARM GRIST MILL.

**MILLS.** CORN, BONE, COFFEE, CIDER,  
DRUG, FAN, SUGAR, WHEAT, WIND.  
**A. B. COHU, 197 Water St., N. Y.**

**SEEDS**—Hints About—Free.  
**A. B. COHU, 197 Water St., N. Y.**

**A. B. COHU, 197 Water Street, N. Y.**

**HARROWS.** **A. B. COHU,**  
**WHEELBARROWS.** 197 Water Street, N. Y.

**AMERICAN VEGETABLE FIBRE CO.**

**FLAX & HEMP RESTORED TO AMERICA!**  
Great Impediment removed from Flax and Hemp in the  
United States, by the Machine of the American Vegetable  
Fibre Co. Each of the Awards above named was accom-  
panied by the warmest approval of the Judges examining  
the Invention. The speed of its action, and the complete-  
ness of its work, surprises all witnesses. The dependence  
on coarse hand labor, which destroyed our trade for nearly  
50 years, is now removed by the substitution of this most  
ingenious Machine, which will fill the dreary gap between  
the cultivation and manufacture of these and similar Fibres,  
and thus restore to us the long lost "Golden Fleece." Illus-  
trated Pamphlets, giving full particulars, sent by mail on  
application to **American Vegetable Fibre Co.**  
**JOS. F. DUNTON, Manager,**  
213 South Front St., Phila., Pa.

## CHICAGO SCREW PULVERIZER.

Does Pulverization pay?

**ABILENE, KANSAS, Nov. 10, 1879.**  
I seeded 3,400 acres of wheat with these machines...The  
stand of wheat is now the best I have ever seen on new  
land.  
**R. J. WEYMES, Trustee.**  
**DANVILLE, ILL., Dec. 4, 1876.**  
This year I harvested, on 190 acres, 6,100 bushels of wheat.  
...In my opinion the Screw Pulverizer increased the crop  
one-third over what I could have got by any other method.  
**D. G. MOORE.**

Send for pamphlet with cuts, and over sixty letters from  
men who have the machine. Address,

**Chicago Scraper & Ditcher Co.,**  
34 METROPOLITAN BLOCK, CHICAGO, ILL.

## La Dows Jointed Pulverizing & Smoothing DISC HARROW.

Being jointed in the center, is adapted to both  
smooth and uneven surfaces. Acknowl-  
edged the best of the kind, and will pul-  
verize and cover seed better in one  
operation, than going over twice  
with others. Made with both Chill-  
ed Metal and Cast Steel Discs  
polished. Send for circular and  
price list. Manufactured by  
**WHEELER & MELICK CO.,**  
Albany, N. Y., for the United States.

By **EVERETT & SMALL, Boston, Mass.,** for the N. E. States,  
and by **Rudolph & Co., Aurora, Ill.,** for Ill., Iowa, Wis.,  
Minn., Neb., Kan., and Mo.

## Powell's Iron Fence Posts

For Barb Wire, Iron, or Gas Pipe Fencing.

Cheap, Strong, and Durable. No Digging Required.

DIRECTIONS FOR SETTING POSTS.

First drive post with wrought iron guide in place, then drive cross-pieces through guide, which renders it  
more immovable than any other post, in the setting of which the ground must be displaced.

We make Line Posts, also End and Corner Posts, either painted  
or galvanized, and Wire Strainers of an Improved Pattern.

**ABRAM G. POWELL & CO.,**  
829 Willow St., Philadelphia, Pa.

PAT'D APRIL  
1st, 1879.

## STEEL BARB FENCE,

Solves the FENCE Problem by meeting all the requisites of

**THE PERFECT FARM FENCE.**

Every Land Owner  
should not fail to examine  
the merits of this fence. It  
is cheaper than all others.  
Easiest handled, and in fact  
just what the people of the  
treeless States have needed  
for years.

To All Inquirers.

It is an impassable barrier,  
yet harmless. Prohibits tres-  
passing. It can be put up by  
any one, and is compactly put  
up for transportation. In  
fact, it is the only fence dog  
and wolf proof.

Cheaper than Wooden Fences. Imperishable when once in place. Indestructible by the  
Elements. Waste no soil by SHADE. Has no Weedy Fence Borders. Shelters no Enemies  
of the Crops. A Protection at all seasons. It is easy of Construction. It needs no re-  
pairs. Accumulates no snow-drifts.

## A STEEL THORN HEDGE.

Impassable Barrier. Prohibits all Trespassing. It can not be destroyed by fire,  
wind, or flood.

100,000 miles of Barb Fence have been erected in 1876, 1877, 1878. Agricultur-  
ists, Herdsmen, Sheep Husbandmen, Ranchmen, Vineyard Proprietors,  
Orchardists, Nurserymen, Railroad Companies, Road Proprietors,  
and all owners and occupants of soil and areas to be protected.

Manufactured by **Washburn & Moen Manufacturing Co.,**  
**WORCESTER, MASS., and 21 CLIFF ST., NEW YORK.**

Received Medal  
AND  
HIGHEST AWARD

OF MERIT  
AT  
CENTENNIAL.  
Send for Catalogue.

## STEAM ENGINES,

**A. B. FARQUHAR, York, Pa.**

Cheapest and best for all pur-  
poses—simple, strong, and du-  
rable. Also Horse Pow-  
ers and Gin Gear.

**SAW, CRIST AND COB-  
MILLS, GINS, PRESSES  
AND MACHINERY** gen-  
erally. Inquiries promptly  
answered.

**Fig. 1** Vertical Engines, with or without  
wheels, very conven-  
ient, economical and  
complete in every de-  
tail, best and  
cheapest Verti-  
cal in the  
world. Fig.  
1 is engine  
in use. Fig.  
2 ready for  
road.

## The Farquhar Separator

(Warranted)  
Pura.  
Agricultural  
Works,  
York, Pa.  
Lightest draft,  
most durable,  
simplest, most  
economical  
and perfect in  
use. Wastes no  
grain, cleans it  
ready for market.

AND  
HIGHEST PRIZE  
AWARDED  
SEPARATORS.

THE  
SILVER MEDAL  
AT  
Paris Exposition.

Send for Illustrated Catalogue. Address **A. B. Farquhar, York, Pa.**

IN PRESS.

New and Revised Edition.

The Best Book on Dogs Ever Published.

A SUPERB VOLUME.

## THE DOGS

OF GREAT BRITAIN, AMERICA, and

and Disease, comprising all the essential parts of the  
two Standard Works on the Dog by

STONEHENGE.

Thereby furnishing what now costs \$11.25 for \$2.00.

It describes the best Game and HUNTING GROUNDS IN  
AMERICA.

Gives names of the Prize Winners in past Dog Shows.

Contains OVER ONE HUNDRED BEAUTIFUL EN-  
GRAVINGS, embracing most noted Dogs in both Continents.Making together, WITH CHAPTERS BY AMERICAN  
WRITERS, the MOST COMPLETE DOG BOOK EVER  
PUBLISHED.

12mo. Tinted Paper. PRICE, POST-PAID, \$2.00.

ORANGE JUDD COMPANY, Publishers,  
245 BROADWAY, NEW YORK.

IN PRESS.

A Valuable and Timely Work.

American Grape Growing and  
Wine Making.BY PROF. GEO. HUSMANN,  
OF THE MISSOURI STATE UNIVERSITY.

ILLUSTRATED.

The work is in three divisions, or Parts. The First Part is devoted to a description of varieties, and includes all the valuable recent additions to the list; it describes methods of culture that the author finds most successful, as well as treating upon the insect and other enemies, and showing how to combat or avoid them. Part Second gives the experience of others in the grape-growing localities in the different sections of the country, including Texas and California, with other matters of interest. Part Third is devoted to wine making; not an elaborate treatise, but gives such practical directions as will allow any intelligent grape-grower to convert his fruit into wine. The work is illustrated with explanatory engravings, and comes as a most timely and acceptable aid to the growers of native grapes.

PRICE, POST-PAID, \$1.50.

ORANGE JUDD COMPANY, Publishers,  
245 BROADWAY, NEW YORK.

CHAPMAN & VAN WYCK,  
(Established 1849),  
DEALERS IN  
PERUVIAN  
Guano

EXCLUSIVELY,

FOR

\$25 per Ton.

ANALYSIS GUARANTEED AS PRINTED  
ON EVERY BAG.

One Dealer wanted in every town, to whom exclusive ter-  
ritory will be given. Manufactured and for sale by  
BAUGH & SONS, 20 S. Delaware Ave., Philadelphia, Pa.

## MATFIELD FERTILIZER.

This is the only fertilizer containing all the soil elements  
found in each crop. Analysis will prove that they con-  
tain a larger percentage of plant-food elements  
than we claim for them by the lab's placed on each pack-  
age. Six years' experience has conclusively established the  
above fact. Send for circular. A few good agents wanted.  
Address

MATFIELD FERTILIZER CO.,  
13 Doane St., Boston, Mass.

## Pacific Guano.

Having been appointed General Selling Agents of the  
Pacific Guano Company, whose works are at Wood's Holl,  
Massachusetts, and Charlotte, South Carolina, we are now  
prepared to offer for sale this celebrated brand of Fertilizer.  
Made from pure hot-air dried phosphate rock, brought  
direct from the Company's mines at *Chisolm's Island*, it is  
rich in **Bone Phosphate of Lime**, finely ground (a large  
proportion of which is immediately soluble), **Ammonia**  
and **Potash**, besides other ingredients valuable for plant-  
food. Although previously known principally in the  
Southern States, where the sales have steadily increased  
during the past twelve years from 745 tons to upwards of

40,000 Tons in a Single Season,

the successful results of its use in New York, New Hamp-  
shire and Vermont have fully justified us in offering the  
increased production of the Company's works at Wood's  
Holl to the *Farmers of New England*, for corn, wheat,  
grain, grass, and all garden vegetables and flowers.

We call attention to our pamphlets, showing the *special*  
analysis and directions for growing *Sugar Beets*, selected  
from tests made expressly for the *Pacific Guano Company*  
by the most celebrated chemists in this country and Europe.

For sale by our agents throughout the United States, and  
full particulars given by

GLIDDEN &amp; CURTIS,

General Selling Agents,

BOSTON, MASS.

## The Maryland Farmer,

A Monthly Magazine devoted to Agriculture, Horticul-  
ture and Rural Economy. The oldest Agricultural Journal  
in Maryland. Terms \$1.00 per year, in advance. Published  
by EZRA WATKINS, 141 W. Pratt Street, Baltimore, Md.  
*The Maryland Farmer* has a larger circulation and will be  
read by more Farmers, Planters, Merchants, Mechanics, and  
others interested in Agriculture, than any other paper  
which circulates in the Middle or Southern States, and  
therefore is the best medium for advertisers who desire to  
extend their sales in this territory.

phlet. E. TOURJEE, Music Hall, Boston.

## LEWIS' COMBINATION FORCE PUMP.

SHOWING THE THREE MACHINES.

This combination makes three complete machines (see cut). Pump will throw a good sized stream 50 to 60 feet. Has three ft. of hose attached. Is converted into an injector, insect, or Potato-Bug Exterminator in a minute. 100,000 sold in five months. You get three machines, worth at least \$10.00, for \$5.00 for brass, and \$6.00 for nickel-plated, or half-price of any other first-class pump alone. It is the most powerful and easiest working pump in the market. An ever-ready household fire engine. They sell at sight. Agents wanted everywhere. We will send sample. Express paid to any express station in the U. S. or Can. for 30c. in addition to cost of Pump. Weight 4½ lbs., Length 32 in. Our Agents are making \$10.00 to \$30.00 per day. We send the proof. Send for descriptive circular, testimonials, and terms to agents. We furnish the Exterminator alone. Sample machine, post-paid, \$1.25 for zinc tubes, or \$1.75 in brass. One-half pound Paris Green will give an acre three separate dressings.

P. C. LEWIS, Catskill, N. Y.

## Maynard's Rifles and Shot-Guns.

### Our New Off-Hand Rifle.

For hunting and target practice, at all ranges, the "MAYNARD" more completely supplies the wants of hunters and sportsmen generally, than any other rifle in the world, as many barrels can be used on one stock; and for ACCURACY, CONVENIENCE, DURABILITY, and SAFETY, is not excelled. The following are some of the scores recently made at Walnut Hill, by members of the Massachusetts Rifle Association: J. N. Frye, President, in All-Comers' Match, 15 shots, 200 yds, without cleaning, 54545555554455-71; L. L. Hubbard, Executive Officer, 200 yards, off-hand, 455355555-49; O. M. Jewell, 300 yards, off-hand, 5455555-34; O. M. Jewell, 300 yards, off-hand, 5555555-35. For illustrated price list, address

MASSACHUSETTS ARMS COMPANY, Chicopee Falls, Mass.

**NICHOLS, SHEPARD & CO. Battle Creek, Mich.**

Established in 1848.

ORIGINAL AND ONLY GENUINE

**"VIBRATOR"**

Thrashing Machinery and Portable and Traction Engines.

THE STANDARD of excellence throughout the Grain-Raising World.

MATCHLESS for Grain-Saving, Time-Saving, Perfect Cleaning, Rapid and Thorough Work.

INCOMPARABLE in Quality of Material, Perfection of Parts, Thorough Workmanship, Elegant Finish, and Beauty of Model.

MARVELOUS for vastly superior work in all kinds of Grain, and universally known as the only successful Thresher in Flax, Timothy, Clover, and all other Seeds.

SEPARATORS a specialty. Four sizes of Separators, from 6 to 12 horse-power; also 2 styles Improved Mounted Horse-Powers.

52 Years of Prosperous and Continuous Business by this house, without change of name, location, or management, furnishes a strong guarantee for superior goods and honorable dealing.

**CAUTION!** The wonderful success and popularity of our VIBRATOR Machinery has driven other machines to the wall; hence various makers are now attempting to build and palm off inferior and mongrel imitations of our famous goods.

**BE NOT DECEIVED**

by such experimental and worthless machinery. If you buy at all, get the "ORIGINAL" and the "GENUINE" from us.

For full particulars call on our dealers, or write to us for Illustrated Circulars, which we mail free. Address NICHOLS, SHEPARD & CO., Battle Creek, Mich.

## THE FERGUSON Bureau Creamery.

CORRECT IN PRINCIPLE. PERFECT IN OPERATION.

Awarded the International Diploma at the Dairy Fair, 1879.

It maintains a perfectly uniform temperature at 60°.

It increases the production of Butter fully ten per cent.

It makes Butter unexcelled in texture, flavor and keeping qualities.

It requires the least labor of any system.

It will last twice as long as any other apparatus.

It is a perfect Refrigerator for Cream and Butter.

It can be used with either ice or water.

Send for large circulars giving full particulars and many other testimonials.

THE FERGUSON MANUFACTURING CO., Burlington, Vt.

## Cooley Creamer

Awarded Gold Medal at Paris Agricultural Exhibition, 1879.

Butter made by this process awarded Sweepstakes at International Dairy Fair, New York, 1878. Two Gold Medals and First Premium on Dairy Butter at same Fair, 1879.

It requires no milk room. It raises all of cream between milking.

It affords best ventilation to milk. It is more thoroughly made.

It is cheaper. It requires less labor, and gives better satisfaction than any other way of setting milk. Send for "Dairyman," giving full particulars and testimonials.

VT. FARM MACHINE CO., Bellows Falls, Vt.

WELLS, RICHARDSON & CO., Proprietors, Burlington, Vt.

★ USE ★ ONLY ★ THIS ★ THE ★ FIRST ★ AND ★ THE ★ BEST ★

# NOW

## For SPRING and SUMMER OUT-DOOR AND IN-DOOR

# Games and Toys.

## LAWN TENNIS.

LAWN TENNIS is doubtless the finest game for the family now on the market, and people who have lawns, can hardly afford to be without a set. They have never been so low in price and high in quality as this year, and even to the cheapest set, \$10, they are serviceable, lasting for years, and a game that

LAWN TENNIS.

the whole family can enter into; easily learned and affording exercise with amusement.

Write for full instructions and prices, which range from \$10, to \$60. The more expensive sets are also used for the Game of **Badminton**, which is played similarly to Tennis. The cheapest sets are of first-class make and regulation size.

Correspondence solicited.

## BAT AND TRAP.

As here represented, the articles necessary to play this game are *one bat, one ball, and the trap*. Any number of persons can engage in the game, from one to five on a side, and it can be played by ladies and gentlemen, or girls and boys. It can be played on the lawn, meadow, or any place where baseball, lawn tennis, or croquet

are played. The ground need not be smooth as for croquet. It is very fascinating, and has as much variety as any other popular game. **Rules** accompany each game, and they are easily learned.

Price, \$2.00.

Expressage to be paid by the Recipient.

## RABBIT TRANSIT.

This has a most lifelike movement very like that of the animal itself. It has three wheels, which prevent its being easily knocked over, and it can be used by any child old enough to walk. It is neatly gotten up, and is appropriate for an out-door as well as an in-door toy.

Price, 50 Cents.

Expressage to be paid by the Recipient.

## THE VELOCIPEDE AND RIDER.

Height, 14 Inches.

Just what the child wants for the street, park, or yard. In fact it is suitable for use anywhere, indoors, or out of doors. The toy is neatly gotten up and handsomely painted; and it represents, very naturally, a real rider on his velocipede, as he spins along over the ground. It is a remarkably low-priced toy, considering its quality and attractiveness, and should sell well.

Price, 50 Cents.

Expressage to be paid by the Recipient.

Ask your nearest Toy-Dealer for these attractive Toys, or send for an Illustrated List of all our Toys and Games to

ORANGE JUDD COMPANY,

245 Broadway, New York.

## World's ONLY Manufacturer of WHEEL CHAIRS

Exclusively.—ALL Styles and Sizes for Invalids and Cripples

Self-propulsion by use of hands only, in street or house. Comfort, durability, and ease of movement unequalled. Patentee and Maker of the "Rolling Chairs" pushed about at the Centennial. For illustrated Catalogue send stamp and mention *American Agriculturist*. HERBERT S. SMITH, 32 Platt St., New York.

## National Game of 15—16

Sent to any address in U. S. or Canada, post-paid on receipt of 10 cents.

# \$1000, REWARD

For any Washing Machine that will Wash Cleaner, Quicker, with Less Labor and Wear and Tear of Clothes than the  
**ROBBINS FAMILY WASHER AND BLEACHER,** Pat'd Oct. 3, 1871.

THE ORIGINAL AND ONLY PERFECT SELF-OPERATING WASHER IN THE WORLD.

No rubbing required. No more yellow clothes nor hard work on washing day. No more rubbing clothes full of holes. Seeing is believing, and if you will try it once, you will never again wash without it, nor use any other washing machine. It is THE BEST IN THE WORLD, and will wash anything from a lace curtain to a horse blanket, and can not get out of order.

Good Agents Wanted, both Male and Female, to whom Liberal Inducements are Offered. Agents can make from \$10 to \$100 per week.

## INDISPUTABLE EVIDENCE.

### "A SPLENDID WASHING MACHINE."

This is what they call the Robbins Family Washer at the home of the business manager of "Farm and Fireside." Heretofore it required one woman a whole day from early morn till late at night, to finish the washing, and an extra girl to cook. But since we got a Robbins Washer one girl attends to the washing, cooks dinner at the same time, and has all the clothing hung out to dry, and tubs, wringer, and everything put away before 12 o'clock noon. We would pay many times the price asked rather than do without one.—Springfield, O., Farm and Fireside, Oct. 1.

The Am. Agriculturist of Oct., 1879, in an article on Washing Machines and Washers, says:— "The style of which we have had special knowledge is the Robbins Family Washer, which accomplishes the end—a continuous flow of soapy water—in a simple and effective manner. \* \* \* To an intelligent person, one who is willing to adopt whatever promises to be a real help in the hardest of domestic labors, who is determined to make it work if it will work, it can not fail to facilitate washing, and at the same time save much wear and tear of clothes."

Publisher of Farmers' Review, Chicago, Ill., received a sample, and after giving it a trial, sends for \$24 worth for his friends and neighbors.

The publishers of the New York Christian Advocate, after receiving sample washer, say: "It requires to be honestly tried a few times only to convince the housekeeper that she has found a friend and economizer of labor in the Washer. The N. Y. Witness says: "Several of our staff have the machines in use, and are well satisfied with them."

N. Y. Weekly Sun says: "The Robbins Washer and Bleacher is as represented."

The Toledo Blade says: "We believe it to be one of the greatest inventions of the age."

The Chicago Inter-Ocean says: "The company could not well say less of that truly wonderful article, which is destined at no distant day to work a complete revolution in the method of accomplishing the family washing. We speak from our own knowledge, as well as from the testimony of thousands who have already availed themselves of its services."

E. B. Mack, N. Y. office of the Cincinnati Gazette, says: "I have one in use in my house and it does admirable work."

112 FULTON STREET, NEW YORK.  
 Please send another Washer. My wife says it is a perfect success. Clothes don't want any rubbing after boiling them.  
 J. THROCKMORTON.

CAMPTI, La., Jan. 23d, 1880.  
 "My wife would not take fifty dollars for ours."  
 J. H. HILL.

SOMERSET, Ind.,  
 "I received the Washer and Bleacher in December, 1879. We wash with it every week, and our folks think they could not do without it. It is a splendid washer."  
 J. W. LINDSAY.

WE COULD FILL THE COLUMNS OF THIS PAPER WITH SUCH EVIDENCE.

The above is no boastful offer, made only for the sake of selling our Washer, but, on the contrary, we mean exactly what we say, and will really give \$1,000 for any washing machine that can be proven better than ours before a competent committee. Any reader who doubts our ability to do all we agree, can easily be convinced by referring to the Mercantile National Bank of this city, to any express company in New York, or to the publishers of this paper.

SAMPLES PREPAID TO YOUR NEAREST RAILWAY EXPRESS OFFICE in any part of the United States east of the Mississippi and Missouri rivers, also in Kansas and Nebraska, for \$3.50. West of that line as follows: In Dakota, at Bismarck, or Yankton, for \$3.50; in Wyoming, at Cheyenne, for \$3.50; in Idaho, at Franklin City, for \$4.50; in Colorado, at Denver, or Pueblo, for \$4; in New Mexico, at Santa Fe, for \$5; in Arizona, at Prescott, for \$3.50; in Utah, at Ogden, for \$4; in Nevada, at Virginia City, for \$5; in Louisiana, at New Orleans, for \$3.50; in Arkansas, at Little Rock, for \$3.50; in Texas, at Corsicana, for \$4.50; at Texarkana, Denison, or Sherman, for \$3.50. In California, at San Francisco, Sacramento, Marysville, or San Jose, for \$4. Our reason for so doing is to induce people to investigate this matter, feeling assured that a trial will secure an agent for us. Send for a sample and secure A BUSINESS THAT WILL PAY YOU WELL.

When you order or write, mention this paper. Address

## W. S. BLUNT'S Universal Force Pumps.

Secured by letters patent.

THESE PUMPS HAVE RECEIVED THE "MEDAL OF SUPERIORITY." The highest award of the American Institute for 1878 over all competitors.

These pumps have enormous power, and are for the house or for out-door wells of any depth. They are constructed with special regard to strength, ease of working, and durability. They can be immediately changed from lift to force pumps, and the air chamber can be removed, so as to allow the handle to work at any desired angle with the spout. Having close tops, they cannot be tampered with. Attention is called to our new elegant pattern **DEEP WELL non-freezing FIRE PUMP.** Also, Blunt's Sand Vacuum Chambers.—A complete protection against sand and gritty water in dug or driven wells, pits, mines, and rivers. For hand or steam pumps, all sizes, from 1½-inch to 4-inch suction pipe.

Send for circulars to

DANL. F. BEATTY, Washlughton, New Jersey.

# Mapes's Tobacco Manure. (Conn. Brand.)

Ammonia, 5.75 per cent; Phosphoric Acid, 7.75; Potash, actual, all in the form of the highest grade Sulphate of Potash, 7.75, equal to 14.33 Sulphate of Potash; Lime, Soda, Magesia, Sulphuric Acid, etc., 78.75.

Price per ton, 2,000 lbs. (bags 200 lbs.) \$52.00.

This is a Complete Manure for Tobacco, and has been repeatedly used alone with the best results. If used in connection with stable manure, reduce the usual quantity one-half.

DIRECTIONS FOR USE.—Apply broadcast, harrowing in; if used near the plants let it be well distributed and mixed with the soil.

**TOBACCO.**

Have used the Mapes Complete Manure for Tobacco for two years. Can grow with it a leaf of SUPERIOR QUALITY at less than one-half the cost of stable manure.

Report of G. H. & J. H. Hale, Nurserymen and Growers of Strawberry Plants:

SOUTH GLASTONBURY, CONN., Dec. 1st, 1879.  
CROP.—Tobacco, put in June 21st. SOIL.—A sandy loam. SEASON.—not favorable to a perfect crop of tobacco. Applied 1,500 lbs. per acre of the Mapes Complete Manure for tobacco, used alone, broadcasted, and worked in with a wheel harrow. Yield, 1,800 lbs. per acre. Quality, the best with one exception of any crop we have had for the past 15 years, having a very fine silky texture and of the rich brown color, now so much in demand by dealers and manufacturers.

Remarks.—Having used the Mapes Complete Tobacco Manure for the past two seasons, we are fully convinced that it is for our interest to use it in future instead of stable manure, as we can grow with it a leaf of superior quality at less than one-half the cost, to say nothing of the time saved in the application of the Mapes Complete Manures.

From \$128.60 invested in your Tobacco Manure (Conn. Brand), we produced a crop, which at the price we have sold it for, although it at this date is not all stripped out, yet, estimating the balance to weigh in the same proportion as that already stripped, will bring us a little over \$1,000.

**TOBACCO.**

Report of John W. Doten.

SOUTH WINDSOR, HARTFORD CO., CONN., Dec., 1879.  
Used 2,000 lbs. of your Tobacco Manure (Conn. Brand), on sandy loam—applied the fertilizer broadcast and harrowed in. Tobacco planted June 15th. Used 1,600 lbs. per acre of the fertilizer. It proved to be the best fertilizer for tobacco I ever used. My tobacco commenced growing before I left the lot, after I set it and never stopped until I cut it, August 15th. I think the crop was the best I ever raised.

For additional letters from Tobacco Growers, see pamphlet 1880. Pamphlets mailed free. Address

Four Copies \$5.—Single Number, 15 Cents.

VOLUME XXXIX.—No. 5.

NEW YORK, MAY, 1880.

NEW SERIES—No. 400.

THE NOON-DAY HOUR ON THE FARM.—DRAWN BY R. E. ROBINSON.—Engraved for the American Agriculturist.

The human system taken in all its parts is a very wonderful self-governing, and at the same time, dependent machine. In order to keep this machine in good running order—and we are using the term machine in the highest sense—it must have food and rest. All experiments that have been tried to test the results of the absence of food upon the animal system, have ended, if carried to their fullest extent, in the same manner with that so often quoted experiment in horse keeping, in which, as related by the owner: "Just as I had got him so he would get along on one straw a day, he died." The system will assert its demands for food in the severe pangs of hunger, and the lack of rest will make itself known in involuntary sleep. Out of these necessities of the case, there has grown the common-sense custom of "taking a nooning" of an hour or so in the middle of the day, in which the system is replenished with food, and the nerves

and muscles refreshed by a period of inactivity. A Spanish-American town is in mid-day hours as quiet as one in New England on the Sabbath. One from the North in visiting such countries is apt to look upon the people as indolent, but he soon falls in with the custom, and finds that the *siesta*, as the noon-day nap is called, and which is taken by the richest and poorest alike, is not a manifestation of laziness, a mere habit, but a wise compliance with the demands of the climate.

In the above engraving of an after-dinner scene upon the farm in early summer, or in "hoeing time," as we sometimes say, the artist has attempted to show the manner in which different members of the family pass the noon-day hour. The hired man is spending his time in the companionship of his pipe, while his thoughts may be wandering in a foreign land from which he came not many months ago. The boys—and by the way,

who enjoy a long nooning more than they—are stretched upon the grass, one with a book, while the other is having a good time with old "Rover"—the joy of the young farmer's heart, and the best sheep dog in the neighborhood. The scene at the well is—well!—the old, old story?—we will let well enough alone. The head of the family finds his rest in the newspaper, and is refreshed with the knowledge of the doings of the great and active world beyond the boundaries of his farm. In the half hour dividing the labors of the morning from that of the afternoon, he acquires a fund of information that keeps him abreast with the world, and alive to the importance of his own calling. A little time thus taken from the toils of the day refreshes and strengthens the man, and makes the whole life fuller, and, therefore, nobler and better. The Noon-day Hour should not be a time of thoughtless inactivity, but a period of intelligent recreation.

**Australian Meat in England.**—A steamer freighted with beef and mutton from Australia recently arrived in England after a successful voyage, the meat having been kept in excellent condition by the cold air process used here in transporting dressed meat from Chicago to the Eastern markets. Naturally the English people will prefer to purchase of their own colonists provided it does not cost anything for the patriotism. This source of competition is a matter of special interest to the American raisers and exporters of meat.

## AMERICAN AGRICULTURIST.

NEW YORK, MAY, 1880.

## Hints for the Work of the Month.

[The Hints and Suggestions in these columns are never copied from previous years, but are freshly prepared for every month, from the latest experience and observations, by practical men in each department.]

May is a very busy month, and there is so much work crowded into it that a farmer is in danger of being in a hurry. Every hour of work should be so planned that it will tell most effectually, and this requires considerable thought in order to do the most urgent and important work first, and leave undone those things which may be done almost as well by and by. As we sow so do we reap, and as this is the month of sowing, the work now will in great measure determine what the harvest of the year shall be. Keep pushing on, but with a plan.

**Labor.**—It must be admitted by every one familiar with farm work, that the labor problem is a difficult one, and it may fairly, from its importance, claim the first consultation in deciding upon the plan of operations for the year. The largest possible crops may not return a profit, if the labor in their production has not been well planned. One of the most important advantages obtained from a systematic rotation of crops, consists in the judicious distribution of labor throughout the year so that there may not be a surplus at one time, and a deficiency at another that will require the employing of extra hands at the highest wages.

**Corn.**—In the Northern and Western States, corn planting will be the leading occupation of the month, but this should not prevent a fair share of attention to other crops that will be needed as a reserve when pastures are getting short, as well as to furnish a variety of feed for winter's use. A soil in high condition, and thoroughly prepared, will give the best promise of a good-paying crop of Indian Corn. The previous cropping of the soil, will have an influence upon the crop, which is nearly as important as the immediate application of manures. A good clover sod, or a grain, or a root crop, immediately after a fair crop of clover, may be followed by corn with a good prospect of success.

**Plowing.**—The plowing, and all subsequent preparations of the soil for the seed, should be done in

the best possible manner. In turning a sod for corn, any breaks or "balks" in the work will prove an annoyance in after cultivation, and should be avoided. In many localities, especially at the West, the Kentucky Blue Grass (*Poa pratensis*), is a troublesome weed in a corn crop, and it can only be subdued by careful and thorough tillage.

**Manures.**—Corn, unlike the other cereals, will bear the direct application of manure in liberal quantities. For immediate results, well rotted manures are always best, but that taken unfermented from the barn-yard may be applied to corn. Long manure may be placed under, while short manure may be spread upon the surface and worked into the soil by the harrow and cultivator.

**The Time of Planting Corn** will of course vary with the locality, but it will be better, as a rule, to secure a thorough preparation of the soil before putting in the seed, even if it somewhat delays the time of planting. Late planted corn, in a warm well pulverized soil will usually take the lead of that which has been struggling from an early start under unfavorable conditions.

**Insects.**—The Potato Beetle has become such an abundant and troublesome pest that it should be given no quarter—not even from the start. By combined effort in the early portion of the season the "bugs" may be kept in check and thus do very little damage. Paris Green has been so long and successfully employed that it is scarcely necessary to explain its mode of application. Suffice it to say that the liquid method is the one now generally practised, that is, mix the Paris Green with water and sprinkle it upon the vines. A coffee pot may be converted into a sprinkler by providing the spout with an extension and a rose at the end. The only source of danger is in the careless handling, and the poison should be kept and used with a full knowledge of its nature.

**Hills or Drills.**—On clean land drills may give the best returns, but if weeds are plenty, hills will be better, as they allow of cultivation in two directions.

**Seed** about which there is any doubt, should be tested before planting to ascertain whether it will grow. Badly kept seed often causes disappointment from its failure to germinate.

**Manure** may be sown early this month. Our practice has been to sow in drills 30 inches apart, using six pounds of seed per acre. A liberal supply of seed is required to secure an even stand, and the plants should be thinned by striking a broad hoe directly across the drills so that single plants will stand 12 to 16 inches apart. Root crops are often a failure from defective thinning.

**Clover.**—An early rolling of clover to settle the roots that have been raised by frost will be especially appropriate after the open winter just passed. Fifty pounds of plaster per acre will often have as good effect as the larger doses of 100 and 200 lbs. that are recommended. Wood ashes on many soils will be found an useful application.

**Meadows.**—Pick up any stones that may have been raised above the surface from the action of frost. The roller may be used to bring the surface into good shape for the mower. Meadows are frequently injured by the tread of cattle before the ground is fairly settled. The grazing of meadows in spring is at the expense of the hay crop. It is better to keep cattle in the barn until the pastures are ready to furnish them a full ration.

**New Fodder Crops.**—The *American Agriculturist* has called attention to the new fodder crops as they have appeared. It is very desirable to have a plant that, with no more trouble in cultivation than fodder corn, shall yield 3 to 6 times as much from the same land. The most promising plants for the Northern States are the different varieties of "Durra," called Egyptian and China Corn, Pampas Rice, etc., and the Pearl or Cat-tail Millet. Experiments with these on a moderate scale may be useful, while as

**Fodder in the Southern States** the Guinea Corn (*Sorghum Halepense*) is esteemed by many, and the Teosinte (*Euchleena luxurians*) described in January last, promises to be of great value. It is not too late to form an estimate of its value, and should it be desirable, to raise a stock of seed for next year.

**Cow Peas**, this great fodder crop of the Southern States, which in renovating land there, takes the place of clover, and is worthy of more attention than it has yet had from northern farmers. Though we can not plow under two crops the same season, we can easily get one, and a heavy one, whether for feeding or for turning under. Two bushels of seed to the acre, and plowed under with a shallow furrow, is the usual quantity. Another method practised at the South is to put in the seed, at the last hoeing of a field of corn, and as soon as the corn is off of the ground the pea crop is plowed under.

**Jerusalem Artichokes** are growing in favor; they are relished by nearly all domestic animals. They may be left in the ground all winter, and when dug in early spring are crisp and fresh and the most acceptable change in the feed. The round, short variety called "Brazilian" is best. The seed is cut the same as potatoes, furrows made 3 feet apart, and the pieces dropped about 12 or 15 inches apart in the furrow and covered with a few inches of earth.

**Sorghum**—The introduction of the early Amber Cane, has again turned the attention of farmers to raising their own "sweetening," and no doubt many will make a trial of it, who have never grown Sorghum, or even seen it growing. As the Amber is evidently vastly superior to the older varieties, to avoid disappointment, be sure to get seed of the true sort. Seedsmen of good reputation, and the makers of sugar machinery, can supply it.

**The Seed**, to make sure of its good quality should be tested, by sowing 20 or more seeds in a box of earth kept in a warm place, as the kitchen window, and noting the number that germinate.

**Land for Sorghum** should be such as would produce a good crop of corn, and prepared in a similar manner. The ground for early Amber is checked off 3½ feet each way, taking care to check it regularly, so that the crop may be easily worked both ways; with these distances, about two pounds of seed to the acre will be required. By "hills," no elevation of the ground is meant, but the term is in common use for the spot, or place for the seed. For Sorghum the ground should be level. About 10 or 12 seeds are to be dropped in a place, and covered.

**Early Cultivation** is necessary. The time for planting is the same as for corn, or whenever the soil has become sufficiently warm to allow the seed to germinate at once. Observe that the plant, when it first appears, looks so much like grass, that a careless hand might take it for a coarse grass, and treat it as a weed. Success with the crop depends upon giving the plants an advantage over the weeds at the start, and to do this, cultivation should begin as soon as the rows can be seen. Whatever implements are used for the corn crop, may be used to till the Sorghum, but hand-hoeing will be necessary at first. At the second working of the crop, thin out to 5, or at most 6 stalks in a hill. When the plants get to be 3 feet high, the crop is left to itself until it is time for cutting the canes.

**Manure**.—None of this valuable substance should go to waste. Any manure scattered over the yards should be raked into a heap and secured from exposure to rain, or put at once upon the field.

**Sheep**.—Sheep should be tagged before turning out to grass. Dry ewes may be fattened, and marketed as soon as possible. Lambs that are for early market, will need the best of care and extra feed. The good shepherd will look well to his flock, and count it every day, so that no animal may get strayed far away and lost. The best way to kill ticks is to dip the lambs shortly after the sheep are sheared in Tobacco Water to which Sulphur is added.

**Washing Sheep**.—A deduction of about ¼ is made by the wool buyers for all unwashed fleeces, and this is right if the washing is properly done. Take it all in all it is best to wash the sheep, though there may be cases where it is not convenient, expedient, or even safe.

**Live Stock**.—Keep live stock of all kinds in a thriving condition. The change from hay to grass is critical, often resulting in loss of condition.

**Crows**.—These birds are in the main the farmer's friends; but at just this time when the corn is coming up it is hard to think so. Crows are great lov-

ers of young corn, but for most of the year they feed on insects that are injurious. Drive them off the corn field, but it is not wise to kill them.

**Machinery**.—See that all haying and harvesting machines and implements are in good condition for service, that they may be ready when wanted. If any portions need replacing, procure these well in advance of the time when they will be needed for use.

## Notes on Orchard and Garden Work.

### Orchard and Nursery.

**Planting** should in general be finished before the first of May; but trees that have been carefully heeled-in may be set safely for some time to come.

**Grafting** can be done now, but great care is necessary. As the bark peels easily at this season it should be cut through with a knife, and the saw made to follow the cut, otherwise the bark may be peeled and a bad wound made. It is not best to remove all the buds from the stock before the graft starts, as there will then be no inducement for the sap to flow upwards. After the union of the graft is made and the buds upon it have started, all those upon the stock below should be removed, in order that the graft may have the full supply of sap.

**Insects**.—An increase of insect life will come with the warmer growing weather. The eggs of the

**Tent Caterpillar** will hatch into the "worms" which will begin at once their ravages upon the foliage. Fortunately these destructive caterpillars put up "a sign," without which they might escape notice. They pitch their "tents" at once, and though these are at first small they may be readily seen in the early morning when the dew makes them conspicuous. Take the tent when the whole family is "at home" and crush it under foot. Various devices are suggested for this, but the hand, with or without a glove, is the best. For the higher limbs a pole with a swab attached may be used.

**Curculio** of the plum stings the fruit while it is quite small. The trees should be jarred in early morning, beginning when they are just passing out of flower, and the sluggish beetles caught on a sheet opened beneath the tree for the purpose. Afterwards those caught on the sheet should be burned.

**Borers**.—Their presence is known by the sawdust they make. The only effectual method of reaching them is by probing with a wire; cutting the tree with a knife as little as may be found necessary.

**Canker Worms**.—Bands of stiff paper put around the trunks upon which is smeared a ring of tar or printer's ink, will keep the wingless females from ascending the trees. The bands will need new coats of tar or printer's ink now and then.

**Plant Lice**, which often crowd upon the growing tips of the branches of cherry and other fruit trees, are removed by syringing with tobacco water.

**Thinning Fruit**.—The sooner fruit is thinned after it has set, the better it is for the tree, as all growth of fruit costs effort for the tree to make and is therefore exhaustive. No one who desires the choicest fruit will fail to thin an overloaded tree.

**Light** is a quick comer which gives no warning. The best that can be done is to cut away the portion "struck," down to the live wood. If the tree is badly affected it is best to remove it entirely.

**Seed Beds** of fruit and forest trees need close attention to keep the soil loose and the weeds from establishing themselves. The beds, especially of evergreens, will need shelter from the hot sun, which may be provided by a lattice work of laths, or brush may be used, but less convenient in weeding.

**Fanting in Orchards**.—There is a general reluctance to give up the soil of the orchard entirely to the trees. While the orchard is young it is best to cultivate it thoroughly, and hoed crops, like potatoes, roots, etc., can be grown as a present pay for the trouble, but as the trees get older and shade the ground, nothing else but fruit should be expected from the orchard. It is a good practice to pasture hogs in the orchard in clover sown for the purpose, as it is one of the best methods of enriching the soil and at the same time destroying insects.

## The Fruit Garden.

**Blackberries and Raspberries** may still be planted, but as they start early they should have been set before this. Stakes or trellises should be provided to which the canes are to be secured. Novices fail to understand that it is the new canes that grow this year that are to bear the fruit the next season. All suckers are to be treated as weeds unless new plants are desired, when the best ones may be saved.

**Currants and Gooseberries**.—Cultivate the ground thoroughly and give a good mulch a little later in the season. Watch for the "worms" which come from eggs laid upon the under side of the lower leaves, and use White Hellebore, a tablespoonful of the powder to a pailful of water. It is best to seal the Hellebore with a little hot water before adding it to the water in the pail or watering pot.

**Strawberries**.—Keep the soil free from weeds and mellow. So soon as the fruit is well set give the bed a mulch, which will keep the berries from the soil. Hand pull any large weeds that may appear. Set out new beds, if plants are to be had.

**Grapes**.—One healthy, vigorous cane upon a newly set vine is enough. Tie it up securely to a support. Vines are trained so variously that specific directions can not be given. Whatever the method of training it should keep in view and provide for the crop of next year. Generally the fruit-bearing shoots for the present year should be stopped; that is, have their further growth in length prevented, by pinching off the end of the shoot at one, two or three leaves beyond the uppermost cluster of grapes; this should be done very early, as soon as the clusters of buds (often mistaken for young grapes) and the young leaves can be distinctly seen.

**Marketing Fruit**.—Provide all the appliances of quick and proper marketing before the fruit is ready. So much depends upon the appearance of the fruit at the market that neatness and care in so packing it that it will show at its best, will pay. Caution should be given to the pickers that no over-ripe fruit be put into the basket or crates. If the distance to market is considerable the fruit should be in a less mature state than when the market is but a short distance away. Watch the market.

## Kitchen and Market Garden.

Work is apt to come with a rush; there are so many different things to attend to, that unless the work is properly planned, much time will be lost. It happens with many who make a change of residence, that they can not begin gardening until the first of May. These have been obliged to delay the planting of those crops that should be put in so soon as the soil will permit, and will be somewhat behindhand; but with extra effort, and that at once, they may be able to get abreast with the season with most of the vegetables of the garden.

**Asparagus** should be set with a strong, round-pointed knife, and with care that the neighboring younger shoots or buds may not be injured. Cut the bed clean, leaving no small shoots to grow now.

**Beans**.—Plant the bush sorts in drills 18 inches apart, as soon as there is no danger of frost. The Limas are not to go in until the cold rains are over and the ground well warmed. Set the poles 4 feet apart, and afterwards plant four or five beans to each pole, thrusting the seeds into the soil with the eye downward. See that the poles are firmly set.

**Beets**.—Thin the early sown sorts as soon as large enough; the thinnings may be used for "greens." Sow every fortnight until July, and in drills 15 inches apart. Put in Long Blood for winter use.

**Cabbage**.—The hoe and cultivator should keep all weeds from the early crop. Sow the seed in open ground for plants for the late crop.

**Carrots**.—Sow the Early Horn for early use; for the winter supply wait until the ground is warm.

**Corn**.—Plant so soon as the frosts are past, and continue to do so at intervals of a week or ten days, to have a supply of this excellent vegetable through the season. "Triumph" is one of the best sorts.

**Cucumbers**.—Plants that have been started in frames should go out, but protect them if cold nights come. Seed for later crop may be sown in the garden so soon as the ground is warm and dry.

**Egg Plants.**—Nothing is gained by setting plants in open ground until warm weather sets in. Push them with a good supply of rich manure. Liquid manure may be used, and with very good results.

**Lettuce.**—Cultivate the early plants; set out new plants from hot-bed for succession. Seed may now be sown in the open ground for the late crop.

**Martynias.**—Sow seed in hot-bed and set the plants out so soon as well started, or sow later in the open ground. Set about 3 feet each way.

**Onions.**—Clean culture is necessary with this crop. The soil needs frequent stirring, and hand weeding will be required in the rows.

**Melons and Squashes** require much the same treatment as Cucumbers. They are of the tender group of vegetables, and require a warm, dry soil at time of planting. Allow an abundance of seed to each hill.

**Parsley.**—Transplant from hot-bed for early, and sow seed in open ground for late crop.

**Peas.**—See previous month's Notes, and "Peas in Plenty," March, p. 105. Sow a succession for constant table use. The large sorts will need brush.

**Peppers.**—Set out plants when the weather has become settled. A few should be in every garden.

**Potatoes.**—Keep clean of weeds by frequent hoeing and stirring the soil. Use Paris Green or London Purple for the "hugs" as soon as they appear.

**Radishes** will need to be sown every week or so for a succession. Dust with plaster for insects.

**Salsify.**—Sow this month and keep clear of weeds.

**Spinach.**—Keep the first crop clear of weeds, and sow every week or 10 days during the month.

**Tomatoes** should be put in hills 4 feet each way so soon as all danger of frosts is past. Provide some support for the plants before they fall over. A little straw or brush to keep the fruit from the soil may be used if the plants are not supported.

**Turnips.**—The early sowings should be kept clear of weeds, and sprinkled with lime or plaster if the Black Fly appears. Sow seed for a late crop.

**Tools** of all sorts required in the garden should always be in good order and at hand; this last is important, therefore have a place for every tool, and when not in use let it always be found there.

### Flower Garden and Lawn.

**Lawn.**—A light top-dressing of some fine fertilizer should be applied. For this purpose, guano, ashes, ground bone, and nitrate of soda, are all good. Either of them may be used, at the rate of 200 pounds per acre. The best time to apply the soluble manures, like guano, and nitrate of soda, is just before a rain. If there are thin spots, sow grass seed upon them, and rake in. Lawns that are well established, should be mowed once a week, and the cutting left to protect the roots from the sun. Large weeds are best removed by hand-pulling, aided by an old chisel to secure the roots.

**Climbers** are especially useful for decorating, and furnishing shade for verandas, and making screens for hiding unsightly places. Of the woody sorts, the Wistaria, Akebia, Clematis, Lonicera, etc., are among the best. If these can not be waited for, sow annuals, as Cypress Vine, Canary-Bird Flower, Morning Glories, etc., or plant Maderia Vines.

**Annuals** may be sown, and care should be taken to properly preserve names by using neat labels at time of planting, especially with new varieties.

**Perennials** should have been divided last month, as many start early. Old beds should be kept free from weeds, and the soil loose, by frequent hoeing.

**Bulbs.**—Lilies, and Gladioluses, may be planted early, and if a part of the Gladiolus bulbs be kept out for a month, a longer succession of flowers may be had; they should have stakes as a general thing. Cannas, which pass for bulbs, do better if not planted until the soil is thoroughly warmed.

**Wild Flowers.**—Those who take an interest in cultivated flowers, can usually find a place in the garden for a collection of the prettiest of the wild flowers, and find much enjoyment in noting their time of appearance, etc. A "rock-work" is a pleasing feature in its place, which is not on a lawn.

**Castor Oil Plants** are so tropical in their nature,

that they make a fine show, and a few of them should be introduced wherever the garden is large enough. They do best started in a hot-bed and afterwards transplanted to the warm open ground.

### Greenhouse and Window Plants.

The potted plants that are to stand out of doors, should have a partly shaded place, and be provided with a thick layer of coal ashes, to prevent worms from entering the pots from below. The plants in the greenhouse will need shade, and this can be produced by coating the glass with white-wash. Muslin screens will answer in small houses.... Water should be freely used, and the houses provided with an abundance of fresh air.... Fuchsias will serve to decorate verandas and like places, otherwise they had best remain in the greenhouse.... Hanging Baskets will need frequent attention, and should be plunged into a tub of water, and well soaked at least twice a week.... It is safer to keep all choice tropical plants in the greenhouse, than to run any risk with them out of doors.... Clear the house of all insects, and make any repairs necessary, while most of the plants are out.

### Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the *American Agriculturist*, from our record kept daily during the year, show at a glance the transactions for the month ending April 9th, 1880, and for the corresponding period last year:

TRANSACTIONS AT THE NEW YORK MARKETS.									
RECEIPTS.	Flour.	Wheat.	Corn.	Rye.	Barley.	Oats.			
23's	1,354,000	1,556,000	2,579,000	69,000	272,000	935,000

Prices for heeves the past four weeks were as follows:

Week Ending	Range	Larger Sales	Aver.
Mar. 15	8 @ 11½c.	9½ @ 10 c.	9½c.
Mar. 22	7 @ 11 c.	9 @ 10 c.	9½c.
Mar. 29	7½ @ 11½c.	9 @ 10 c.	9½c.
Apr. 5	7 @ 11 c.	8½ @ 9½c.	9½c.

**Beeves.**—The average receipts for the past four weeks, have been a considerable above those of previous months. During the first week, there was a good home demand, with a fair foreign call, thus making the market active, and prices good. The second week was remarkably dull, in marked contrast with the one preceding it, but the prices have held good up to the time of going to press. The first week in April found the markets too liberally supplied, and much money has been lost by Shippers. Oxen sold as low as 3½c. live weight, while Choice and Extra Steers to dress 57, sold at 10½ to 11c.

**Milch Cows.**—The demand rather moderate for fresh milkers, the market remaining quiet and about the same for the four weeks. From \$30 to \$55, represents most of the sales, the latter being choice stock for family use.

**Calves.**—The supply has been liberal, demand very moderate, and the market dull. There was a falling off at the close of the month. Mixed lots sold for 4½c., and common to prime veals, at 4½ to 7c.

**Sheep and Lambs.**—The month opened with good prices and considerable demand, which was soon answered by a full supply, when the market fell, and remained so for a week, with little rise for the last fortnight. Common lambs felt the decline more than sheep. The sheep sold in most part at from 5½ to 7c.; extra wethers at 7½c., and a small lot of selected sheep at 7½c.

**Hogs.**—The month opened steady, and closed moderately firm, with ½c. advance. Common and Prime Hogs, quoted at \$4.75 to \$5.12—Average for the month about \$4.60.

**The Horse Market.**—Last year was the best in the Horse Market for the past five years, but the indications are that the one just opened, will be better than the last. Common work horses are selling at \$80 to \$150 per head. Street car horses are bringing \$110 to \$135—Those animals fitted for carriage horses, have brought as high as \$250, and heavy cart and dray horses about the same.

#### Prices of Feed.

Cotton-seed meal	per ton	\$30.00
Liauseed-cake meal	"	37.50
Midlings	"	24.00
Brans	"	23.00
Corn-meal	"	23.00

#### Prices of Fertilizers.

Nitrate of Potash (95 per cent.), per lb.	9 @ 9½c.
Sulphate of Potash (potash 41 per cent) per lb.	3½ @ 4 c.
do. do. (potash 27½ per cent) per lb.	1½ @ 1½c.
German Potash Salts (potash 12 to 15 p.c.) p. ton	\$15.00 to \$18.00
Muriate of Potash (potash 50 per cent), per lb.	2 @ 2½c.
Nitrate of Soda, per lb.	5 @ 1½c.
Sulphate of Ammonia (21 per cent.), per lb.	4½c. @ 4½c.
Dried Blood (ammonia 13 per cent) per ton	\$40.00 to \$45.00
No. 1 Peruvian Guano 10 p. c. ammonia, standard, p. ton	\$35.00
do. do. Lobs. do. do.	40.00
do. do. guaranteed, p. ton, cargo K.	45.00
Soluble Pacific Guano, p. ton	45.00
Excelsior Fertilizer Works, Fine Ground Raw Bone	55.00
Mapes' Complete Manure (clay soils) per 1,000 lbs.	25.50
do. do. (light soils) per 1,000 lbs.	25.50
do. do. "A" Brand, (wheat) p. 1,000 lbs.	30.00
do. do. Corn Manure, per ton	49.00
do. do. Beet do. do.	49.00
do. do. Cabbage do. do.	47.50
do. do. Tobacco do. do.	52.00
do. do. Fruit and Vine Manure, per ton	37.00
Stockbridge Rye Manure, do.	45.00
do. do. Wheat do. do.	45.00
do. do. Seeding Down Manure, do.	40.00
Bowker's Wheat Phosphate, per ton	40.00
Baugh's Raw Bone Phosphate, per ton	33.00
Baugh's Manure for Tobacco and Grain, per ton	45.00
Walton, Whann & Co.'s Raw Bone Phosphate	40.00
Gypsum, Nova Scotia, ground, per ton	7.50

Premium Clubs already started can be filled up. And there is plenty of time to start new Clubs and complete them.

**Spring Work** is opening, and multitudes will now feel the need of the help, the hints and suggestions given by practical men in the pages of the *American Agriculturist*. They only need some one to present the paper to them and take their Subscriptions. The Premiums will well pay those who do this for their trouble.

containing a great variety of Items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of room elsewhere.

#### What This Number Contains:

Most of our readers are too busy, just now, to at once go through the hundred and fifty or more articles and items of this paper—each one doubtless worth reading. All will first turn to

Hints for the Work of the Month, on pages 172-3-4, as suggestions from practical men are scattered through those pages. Bee men will look at page 178.

Corn, our great national crop, comes to the front this month. Prof. Atwater's results of experiments, and the value of corn as a renovating crop, pages 180, 181, will be carefully studied, with profit. See "Basket Item" on Corn, page 173.

Dairy Matters are treated at length, and variously, on pages 184-5. A famous cow is described on page 183.

A Cottage or House for the Country, costing \$1,500, on page 182, will interest many, especially as the detailed specifications are given.

Huntings of various "species" have their "Gallery" on pages 176-7.

The Hints and Helps to Farmers under several heads, on pages 186-7-8-9, can scarcely fail to supply some useful hint, in one way or another, to every reader.

Fences and Fencing, on pages 179-80, give a few readers' experiences in their own words.

"The Department of Agriculture" will scarcely enjoy the exposé, on page 190, but many of our readers will.

Some Newer Grapes, pages 190-1, and the Great Grape Enemy, pages 192-3, will find very interesting by many readers.

Housekeepers are not forgotten, as witness pages 194-5.

The Boys and Girls will find things useful, things puzzling, etc., on page 196-7-8.

The "Basket" abounds in condensed items in two places, on pages 175-6-7-8-9, and over on pages 203-4-5.

**Where to Get Things Wanted.**—Many thousands of letters come to the Editors every year (some with and some without "return postage"), asking where they can obtain from trustworthy parties, implements, animals, poultry, seeds, plants, fertilizers, and a great variety of other things, all of which questions we try to answer when we can. But nine out of ten of these letters, and much valuable time of both writers and respondents, would be saved, if the inquirers would take the little trouble required to just look through the advertising columns, where usually, in one number or another, several parties announce the very things asked about. We try to keep out all parties not trustworthy. If any mistake occurs, after all possible care, we can only acknowledge to having been deceived, for we do not admit any advertisers whom we would not ourselves patronize when wanting the things they offer. (The Editors have the "veto power" over any and every advertisement proposed for these columns.) It will always pay to read through the business columns to see what is offered and by whom, and useful hints are often derived from reading what others say and how they say it. New ideas are thus started up in one's mind.—When corresponding with any of our advertisers, or sending for catalogues, etc., it is well to state that you are a reader of this Journal. They will know what we expect, and what you expect of them as to prompt and fair treatment.

**The Sugar Beet**, by Lewis S. Ware, C. E. M. E., etc., Philadelphia, Henry Carey Baird & Co. Just as we go to press the work with the above title comes to our notice. At no former time has the Beet Sugar interest in this country been so full of promise. It appears as if the period of costly failures had passed. The few establishments now at work though small are successful, which is more than could have been said at any former time.

There is probably nothing more certain in the future of American agriculture, than that it shall supply the country with sugar. Whether this is to come from the Beet, from Indian Corn or from some variety of Sorghum already or yet to be produced, we do not undertake to say, or whether the consummation will take place in 10, 50 or 100 years, matters not: it is bound to come—and the sooner the better for both the country and the farmers. Hence we look with special interest upon any thing that tends to increase the knowledge of sugar-yielding plants, a purpose which this work is admirably calculated to serve. Though we have had no time to read the work, we can see that it is marked throughout by thoroughness and competent knowledge. It is not a work upon sugar making, but upon the Beet itself in all its relations; its composition, varieties, culture, enemies, harvesting, storing, the uses of the root itself and the waste products from the factory, the pulp, for feeding. In fact, all that can be said about the beet that the grower need know is given here, and illustrated liberally and handsomely. It is not a reproduction of a foreign work—though foreign authorities are quoted when desirable—but a large share of the matter is from the author's own experience. Sent from this office, post paid for \$4.00.

#### Keeping one Cow—The Prize Essay.

On account of the large number of essays (over 70) and their fullness, it has been found impossible for the judges to make a report in time to announce the prizes this month, and we are obliged to wait until our next issue, in which we expect to print the one awarded the first premium. This will doubtless alone be worth more than a whole year's subscription to the hundred of thousands of people who keep one or more cows.

**Feeding for Milk When Dry.**—A cow should be as well fed while dry as when giving milk. She should now increase in flesh, so that she may be able to give a greater flow of milk when milking time comes. To feed a dry cow the poor hay, or even think that straw is good enough, is poor policy, and the loss will show itself in the milk pail. Feed the cows well all the time.

#### Oleomargarine—What it is and What it is Not.

When Oleomargarine was first manufactured we described the process, but that was some years ago. Recent inquiries make it necessary to say something more about it. Prepared beef-suet, the membranes, etc., removed, is churned with milk to give it the flavor of butter, is colored and salted—that is what it is—beef-fat prepared to look and taste like butter. It has not the mechanical texture of or the chemical composition of, and is in no respect, butter. So far as it is sold as butter it is a miserable fraud. The makers claim that it is as good as any butter and much better than a large share of the butter sold. That is a point with which we have nothing to do. It is *not* butter, as that is a product of the cow, obtained through the medium of the milk, and contains several constituents that the fat of the cow does not and which can not be added. Several of the States have passed laws directing that all the packages of Oleomargarine shall be distinctly marked with the word in letters of a given size. This is well, so far as it goes, but does not prevent the retailer from serving it as butter. As oleomargarine can be made at a much less cost than butter can be produced, the sale of it as butter is injurious to the dairy interest, and every dairyman and every farmer is interested in preventing its sale as butter, and to this end a petition is being circulated for signatures asking Congress by a general law to place restrictions upon its manufacture and sale. But the capitalists who have money invested in the manufacture of Oleomargarine are not idle. They have invited the Committee on Agriculture of Congress to visit their factory; they have also invited a number of prominent chemists to do the same; their guests have been steamboat and dined and we suppose wine, all after the approved fashion. We do not know what the effect will be upon the Congressmen, but we are very sure that the chemists will say, as they might have said before—"Gentlemen, your stuff is not injurious, it is as healthy as beef-fat need be, we see no objections if people wish beef-fat with their bread, why they should not buy yours, but it is not butter and no amount of steamboat or banquet can make us say that it is."—We see no reason why colored and salted beef-fat or colored and salted hog's lard, or purified and salted palm oil should not be eaten if one's taste runs that way, but they should not be sold as butter or given out to one who asks for butter, and the penalty to one who does it should be most severe. We notice of late a disposition to change the name of the stuff to Butterine—no, gentlemen! you chose your own name at the beginning. Oleomargarine is quite a pretty name and as distinct from *butter* as the stuff itself, and we do not wish a name that may lead to the confounding of two very distinct articles. Butter can stand on its own merits, with its own name; let your stuff do the same, and may there may be laws enough to make you do it.

**DON'T FORGET  
THE PREMIUMS.  
2  
Months More.**

**Two Months Yet Remain**, May and June, during which any person who wishes can obtain one or more of the useful and valuable articles offered in our Premium List (of which a copy will be sent free to any applicant not having one). They are easily secured. This has already been done by more than 25,000 persons, who during years past have tried with success the raising of Clubs of Subscribers for our paper, and availed themselves of the liberal offers of Premiums made by the Publishers.

We invite **all** our Subscribers to take hold of this work and secure a Premium while the offer is open. Specimen copies of English or German editions will be sent to any wishing to show them for this purpose.

**Silica in Plants.**—Silica (or sand) has long been considered an essential constituent of plants, especially the cereals like wheat and oats, in which it was held indispensable to give the straw the proper strength to hold up the heavy, well filled heads. The conclusions stated in the Annual Report of the Connecticut Agricultural Experimental Station of 1879, show that the value and importance of Silica in plant nutrition, have been greatly overestimated. The Report says: "1. It has been conclusively shown that the strength of straw does not depend upon the Silica in it, but on the vegetable substance itself. Rapid growth produces, in presence of abundant Silica, a comparatively loose and weak cell tissue. Slow growth, on the other hand, yields in practically total absence of Silica, firm and close textured stems. Again, no fertilizing experiments in which soluble Silica has been supplied, have shown any benefit from the Silica. Finally, there is no element so abundant in all soils, and none whose access to crops is so impossible to avoid. 2. Numerous most careful trials on the growth of plants under circumstances where Silica has not and could not, be supplied by them, except in most minute quantities, have demonstrated beyond all question that Silica is not necessary to the nutrition or complete development of agricultural plants."

**Chicken Cholera.**—The Georgia State Agricultural Society, in answer to the offer of a reward for the best remedy for chicken cholera, received the following, which is of course claimed to be a *cure*. "Gather one bushel of Smart-weed and put it into a large-sized kettle, adding 10 gallons of water. Boil down to three gallons and mix this liquor with meal in proportion of one pint to three gallons of meal, and feed the same to 200 chickens twice a day until disease disappears and then give no more for a week. To keep the disease away give every other day." We give the above for what it is worth, and have no doubt it is quite as valuable as any of the secret remedies now offered. The one who proposes the remedy claims that previous to using this decoction he lost 800 chickens, but none since its use, which is as much entitled to consideration as the claim of secret stuffs to be *perfect cures*. We take it that by "Smartweed," one of the acrid *Polygonums*, is intended. Two species of *Polygonum*, *P. Hydropteris* and *P. acre*, are found in moist ground in nearly all parts of the country. These are known as "Smart-weed," "Water-Pepper," and "Biting Knot-weed." They have a very acrid juice, which irritates and even blisters the skin if applied where that is tender, and has a most pungent, biting taste. Some species resembling these are without this property.

**Winter in Dakota.**—A friend, who is stationed at a post in the Northwestern portion of the Territory, writes in a private letter: "We have had a rigorous winter, lasting from the latter part of October until past the middle of March. For weeks at a time the thermometer never got above zero, but it did one day reach to 51 below. Of course the mercurial thermometer never told us that, it was resting about that time. [Referring to the fact that mercury freezes at about 39°—Ed]. For six weeks we were without mails on account of the heavy snows that completely blockaded the roads. We had storm after storm, such as you in the East never dreamed of, and which pen cannot paint. Yet the weather is glorious! A clear, bracing air that makes it a pleasure to live in it. Zero weather we consider warm, and hardly worth while to put on wraps in going short distances. Of course this refers to quiet weather. A wind alters the case materially. Most of us wore buckskin pantaloons after the manner of the Indians, buffalo overcoats, fur caps and gloves or fur mittens. In very cold weather boots and arctics were unwearable, and boots made of buffalo robe with the fur inside were the only articles for possibly keeping the feet warm. I must, on second thoughts, make an exception, as German socks and loose arctics could be worn. I adopted the former, however, as did the majority. At present writing (March 28th), the Missouri river is still stationary. Ice four feet thick and as clear as a crystal, though in summer the Missouri is the maddest river, without exception, I ever saw."—Ice four feet thick! and in the East an impending ice famine!

**Balky Horses.**—Among the suggestions said to be published by some Anti-cruelty to Animals Society, are these: If the horse when he balks, can have his attention diverted there is usually no trouble in starting him. This may be done in various ways of which the following are a few that have been employed: Take the horse out of the shafts and turn him around several times quite rapidly. This will make him entirely dizzy and lead him to forget that he does not wish to draw the load. A stout twine twisted around the fore-leg has been used as a remedy with good results. A string tied around the ear has the same effect. We have seen horses of the balkiest sort started in a moment by putting a lump of earth into their mouths. Even a piece of sugar or a handful of fresh grass will so divert the attention of a balker that he will often start off without trouble. Some mild

treatment like these that set the animal to thinking of something foreign to his work is vastly better than any amount of whipping, and is much easier of application.

### Sundry Humbugs.

Every now and then a letter shows that all do not understand the rules that govern the conduct of these columns. It is a mere waste of paper and postage to write a request to "denounce so and so in your Humbug Column," as some

thoughtless persons occasionally do. Our older readers are aware that these columns are not and cannot be made the medium through which to redress private grievances. One to merit a place here must be an enemy to the public welfare, not merely suspected of wrong doing, but the proofs against him must be such as would convince any fair minded man that the good of the community requires his exposure. There are—and more's the pity—quite as many of this kind as we care to occupy ourselves with. The publisher of a country newspaper writes: "Dear Sir, Please denounce X. X. X., of Cincinnati, O.," who advertised some gimcrack in his paper and did not pay. If we were to set up as denouncers of all who do not pay for advertising we should be obliged to issue a large supplement. We find that requests like the above, as in this case, generally end with

"PLEASE OMIT MY NAME."

This person expects us, upon his bare request to give one we never before heard of the bad eminence of a place here, and is even unwilling to appear as accuser. No we thank you. We are not in that business just now.

With the spring, when snakes and other creeping things come out of their holes, those sharpers appear who

#### HAVE DESIGNS UPON FARMERS.

Where these fellows come from, and where they stay when not going about the farming districts is a mystery—but soon after the skunk cabbage blossoms these are sure to appear, whether in person or through advertisements, offering one thing or another, but all having the same aim—the farmer's pocket. Sometimes it is

#### WONDERFUL SEEDS AND PLANTS.

It is safe to assume that any seed or plant offered by traveling vendors or agents as something new or of a kind not to be had elsewhere, is a fraud. Valuable new things are not introduced in this manner. Tennessee is a wonderful State in many respects, and the seeds that are advertised by parties in that State are—to say the least, remarkable; so much so that we advise our readers to let some one else try them... Beware of those chaps who come about with "rights" for sale, or some implement or affair for which they would make you "sole agent" for the township. A farmer who properly attends to his farm has no time to bother with selling somebody's Mowing Machine Knife Sharpeners or anybody's Patent Spring Bed. Besides this, nearly all

#### THE SWINDLES UPON FARMERS

through the medium of notes fraudulently obtained, that have come to our knowledge, would have been avoided, had the farmers refused to have anything to do with matters outside of their proper calling. Being tempted by the idea of making money through the sale of articles of which they knew nothing, they have had to pay notes which they signed while thinking that they put their names to an order for goods. So generally are they swindled, that the farmer's only safety is in refusing to buy any machine, implement, or other article, of any traveling agent whatever. There is nothing needed on the farm that may not be bought of dealers, who have a fixed habitation and can be found when wanted.

#### THE TREMONT SPOON CO.

of Boston has come to grief. We noticed its offer last month, and now have to record the fact that the Postmaster General, being convinced that they were using the mails for fraudulent purposes, has issued orders to the Boston Postmaster to deliver no more letters to the men of spoons. Hardhearted Postmaster General! There are other concerns that need looking after, including a Gold Ring Shop in Philadelphia.... The sellers of recipes for making

#### ILLUMINATING OILS

appear to be active, especially in Nebraska and others of the newer States, and the many letters of inquiry make it necessary to repeat our caution against them. They claim that their recipe will allow an illuminating oil to be made at less than half the price of kerosene, and one

that will not explode. As a proof of its safety the chaps have a sample of the oil which they show will extinguish a burning match. We have seen none of these recipes that did not direct the use of Benzine, which is mixed with various useless articles as a blind, and in some cases it is asserted that these remove its dangerous qualities. Benzine is very cheap, but it is very dangerous, and *nothing whatever* can be mixed with it that will make it safe. It does not of itself explode, but its vapor mixed with air will—and murderously. The matter is of such serious importance as to warrant our repeated warnings, for it is not too much to say that it is

#### A MATTER OF LIFE AND DEATH.

Let no considerations of cheapness; let no assurance that any admixture will alter its nature; let no claim that anybody's lamp or any patent burner will make it safe, induce you to have, keep, and much less burn Benzine. Benzine is benzine and is really more dangerous to have in the house than gun-powder—because every one knows the danger of that and is cautious. Good kerosene is cheap enough; if that can not be afforded, rather go to bed at dark than to use benzine in the lamps.

#### ANOTHER STUMP DESTROYER.

Last autumn we gave an account of the wonderful "Stumps Removed" of one Horton, William V. by the way, what has become of William, "Willie we have missed you", that took two nails, a wire, and some of the powder, and the rest was left to electricity. There is a chap going through the Southern States—stumping the country so the speak, with an "exterminator" that beats Horton's all "out of sight." It is Wm. F. Buchanan's "Lightning Sprout and Timber Exterminator." You bore a hole, put in a spoonful—and away goes your tree—that is "within six or twelve months," quite long enough for the seller to get well out of the way. No nails—no wire, nothing but a hole and the "exterminator." We are left in doubt as to what it is, but as a spoonful is used it must be a powder or a liquid. It is called "Lightning," but if 6 to 12 months is Buchanan's idea of lightning, we prefer Horton's electricity, which did it in two or three.... The mention of lightning and electricity as applied to trees and stumps suggests

#### THE WAR OF THE BATTERIES.

Elias still sends out his affidavit that there "ain't no sich pusson" as Prof. J. C. Boyd, while we have every reason to believe there is such a person, for have we not his circulars, and is not his name upon them? And he calls himself a Professor, and he does *profess* at a remarkable rate. One correspondent writes that he would expect a piece "cut from the end of an ear of corn" to do as much good as one of these batteries, and he is right. It is a remarkable illustration of the power of the imagination that people who wear these things think they perceive an effect from them. It is utterly absurd to suppose that wearing any combination of metals that may be put together in the form of a medal can send any electricity into the body. These batteries and the claims made for them show an entire lack of knowledge of the most elementary laws of electricity. Of the two we like Boyd's the best, as he, in explaining his battery, says: "That the various blocks of metal were so placed that when the electricity was formed it would be formed *in gimlet shape*," and that it would "*pass on twisting*." If we are to have electricity, let it be by all means of the "doubled and twisted" sort. The eccentric Rinesque once sent a paper to "Stillman's Journal," describing 15 species of lightning. Had he lived in Boyd's time he could have added the "gimlet-pointed," and thus made 16 species. But these New York Batteries must step aside, and

#### MAKE ROOM FOR A BOSTON BATTERY.

Here comes Doct. Dye, who unites with his battery an absorption pad. Electricity sends disease out of the body and the pad absorbs it before it can go back again. But we can't help thinking what a dangerous thing that pad must be after it has gone absorbing for a while. As the same circular informs us: "It will not wear out," and as we are given nearly the whole catalogue of diseases which it will absorb, we think that the Boards of Health should look after these odd pads.... One of the frauds recently brought to our notice, is an "Artificial Ear Drum." The sender should give us his name (not for publication), and also that of the seller of the "Ear Drums".... Here are several letters from evidently intelligent writers, either making inquiry about, or sending to us as something new, the circular of

#### THE "REV." JOSEPH T. INMAN AND HIS RECIPES.

So far from being new, he is one of the oldest of humbugs. Looking back in our files, we find the first mention of Joseph in November, 1861. How much earlier he began his career we can not say. During all these 16 years we have many times exposed his trick, and at this late day the necessity seems as great as ever. If the fellow ever had a right to the title, Reverend, he has long ago lost it, for he works by trickery, and his circular is a printed lie. These are plain words, but they best express our meaning. His little advertisement of only 7 lines

appears in almost every paper; even those journals that profess to discriminate in advertisements, probably deceived by the "Reverend" part, publish this. It offers "to all who are suffering from the errors," etc., of youth, "a recipe that will cure you FREE OF CHARGE." Of course this is a very taking offer, to be cured and "free of charge" meets the case of a vast number. The applicants for the "recipe" receive a four page circular, which gives the personal history of Rev. Joseph, and tells how he was cured by what he calls the "Corrassa Compound." The "Recipe" we give once more:

EXTRACT OF CORRASSA APINIS.....Eight Drachms.  
EXTRACT OF SELARNO UMBELIFERA.....Four Drachms.  
POWDERED ALKERMES LATIFOLIA.....Three Drachms.  
EXTRACT OF CANADIAN HERBALSIS.....Six Drachms.

Then follow directions to mix it and to keep it well covered, and for taking it. The recipient of this recipe if he takes it to an apothecary, will be told that they have no such articles; he will learn the same story at the next drug store, and so on. If he applies to a competent and educated apothecary he will learn that there are no such articles, that the wonderful recipe is nothing but a useless

#### MERLEY OF ROGUS NAMES,

made up to appear like scientific names, and badly done at that. These names stand for no drug known in pharmacy or medicine, and for no plants known to botanical, or other science. If the disappointed holder of the "Recipe" reads the circular more carefully, he will find that his trouble has been anticipated. He will read on page 3. "As the drug stores can not be relied upon to procure new remedies of pure quality [the scamp!], I can forward the CORRASSA COMPOUND in packages, ready for use (put up safe from observation), to those who need it, at the price which it costs me [Hear him]. My means make me independent. I seek no other reward for sending the remedy than the satisfaction of doing good, and the blessing of an approving conscience" [Good boy!]. We read further: "The cost of each package (including the Government stamp) is Three Dollars and Thirty Cents (\$3.30), [nothing like being particular, that 30 cents gives a charming air of accuracy.] The postage is twenty-one cents. The price then of one package, sent by mail to any address, is Three Dollars and Fifty Cents (\$3.50)." All the rest is unimportant. The "Free of Charge" according to the Reverend Joseph T. Inman is \$3.50. This is his trick, a very mean one it is, as it is nothing more nor less than obtaining money under false pretenses. The fellow advertises to send a recipe free of charge—he sends a recipe which is a printed lie. He knows that the unfortunate can't get his stuff, offers to provide it at a rousing big price—for \$3.30 what probably did not cost him 30 cents—and adds to his cheater's cant about an "approving conscience." Joseph, you are a first class hypocrite. Our friends can help check this fellow's career. Many papers publish his advertisement in ignorance of these facts. Wherever your local paper publishes his proposal, show the editor this story of Inman and his recipe.

#### MORE ABOUT THE BATTERY.

What is said above about the battery was written after an examination of the circular and its engravings. Since then we have pronounced the thing itself, and find it even a worse fraud than at first supposed. We give its "portrait life-size." It consists of a central piece of copper  $\frac{1}{16}$  inch thick, with a scalloped edge; in the middle of this piece is a circular hole plugged with a bit of white metal. Around this copper center are small metal discs of two sizes and of three kinds, arranged as shown in the engraving, where the dark portions indicate copper, the shaded ones brass, while the light portions are of some white metal—but not having a blow-pipe or chemicals at hand, we can not say what kind of two-pot stuff it is. These 14 pieces are set in a white metal ring, into which they are crowded, and are held in place by friction; though we are not sure but the larger white discs have a minute touch of solder. We have been thus particular in showing how the thing is made, as those who have but the most elementary knowledge of electrical action will see at once that it is absolutely

ELECTRIC BATTERY.

#### IMPOSSIBLE FOR ANY ELECTRICITY

to be generated—that is, any free electricity—with these different metals in absolute contact, unless indeed it may be of the "gimlet-pointed" kind, a style unknown to science, however it may be to "Professor" Boyd. There is no more development of electrical action be-

tween these bits of metal than there is between the coins in one's pocket—and we pronounce the thing to be an

#### UTTER BARE-FACED FRAUD.

There is one melancholy feature in the exposure of such successful humbugs—for, so far as the numbers sold go, this has been a success—that is, the comment it suggests upon the intelligence of the community. We make boasts of our popular education, of the general intelligence of the people and all the rest of it. Yet here is a thing, in its structure violating the simplest laws of science, bought and worn by hundreds, who deliberately assert that they can feel its electrical action, and claim to be benefited or cured by it. Yet it can have no more effect than the horse-chestnut carried about their persons by the ignorant, as a "preventive of rheumatism!"

**Peach Trees and Frost.**—A frost at blossoming time ruins the peach crop every year—in the papers. Aside from this regular killing there are seasons in which real damage is done and an actual frost, when the trees are in bloom, must seriously diminish if it does not entirely cut off the crop. Several years ago we suggested that owners of peach orchards try the method of warding off late frosts followed in the vineyards on the Rhine, which is to make a smoke. As a curtain of vapor in the form of clouds will prevent frost, so will a curtain of smoke. The danger of frost is greatest in the hour or two before sunrise; the vines which have been gradually cooling all night, do not reach a temperature so low as to be dangerous until towards morning. Then the smoke heaps are started and a cloud of smoke hangs over the vineyard until the appearance of the sun removes all danger. Fires of brush and wood rubbish are started, and wet straw is thrown upon them to produce a copious smoke. Frost occurs only on calm nights, but even then there is usually a slight current of air and the fires should always be at the windward side. If any have tried this method in the peach orchard we should be glad to hear with what results. It seems a matter well worth testing, and may be of great value.

**A Veteran Peach Tree.**—P. M. Angur, reports in the Middletown, Conn., "Constitution" that he examined a peach tree at the residence of Henry Hart, in Saybrook, Conn., which, at 2 feet 10 inches above the ground, measured 4 feet around. It had four principal branches having the circumferences respectively of  $2\frac{1}{2}$  feet, 2.15 feet, 2 feet, and 1.14 feet—a total of 8 feet, or twice that of the main trunk. The tree has been a constant and abundant bearer.—This indicates that the peach tree is not necessarily a short-lived one, as is generally supposed.

**Hens Eating their Eggs.**—Where this habit has been formed it is a difficult matter to break it up, and it is generally the best and quickest way to kill the hens. If the bird is worth the trouble, a nest may be so arranged that the egg, when laid, will at once roll out of sight and reach. Some one has invented a "bit" to prevent the habit, but we know nothing of its value.

**Late Frosts.**—We expect early frosts, and in autumn accept the damage they do as a matter of course. Late frosts in spring are most disheartening; one crop, which was yesterday pushing forward so encouragingly is to-day blackened and dead, and we have either to begin anew with seed sowing, or with transplanted crops: fall back upon the reserves which the careful gardener preserves for such a contingency. But few are aware how slight a thing will protect from frost. It is the radiation of heat from the plant; its rapid cooling that kills it. In a clear night every exposed thing on the face of the earth is giving off heat, and when these cool down to a certain point, the moisture in the air falls upon them in frozen particles and we call it frost. If the night is cloudy, the cooling is less rapid, the clouds are said to reflect the heat given off; the air may seem as cool, but there is no frost. For tender plants a thin muslin, even a paper, suspended over them, will prevent injury. Tomatoes in the vegetable garden, and a host of things in the flower garden may be saved by the use of a curtain or screen, if only of paper. Whatever will prevent rapid radiation of heat will answer. We once had a bed of tender plants too broad to readily arrange papers upon and frost was predicted. A lot of brush was handy and this was stuck rather thickly in the bed, and then some light hay scattered upon the brush. The plants were saved. The object of the brush was to keep the weight of hay from crushing the plants. The French gardeners build a little straw tent over their tender plants; this is so arranged that the plants can be uncovered by day and housed by night. Cucumbers and other such plants will grow much more rapidly if covered at night. Though not cooled down so low that frost is deposited, they are so much cooled during the night as to seriously check their growth, and if they are covered regularly this is avoided. Frames 6 inches high and a foot square covered with a pane of glass will be found very useful in the garden, especially in forwarding cucumbers and melons. An

efficient substitute may be found in soap, starch, and other store boxes; the cover and bottom are removed and a bit of muslin tacked over the top. Such frames, when their convenience is once experienced, will always be kept at hand, as their cost is insignificant.

**Sorghum—Early Amber.**—The fact that the variety of Sorghum introduced a few years ago as the Minnesota Early Amber, is now called by the shorter name of Early Amber or Amber, is an illustration of our frequent protest against complex names. Life is too short and farmers too busy to say Minnesota Early Amber Cane when Amber Cane will answer the purpose, which is to distinguish the variety. That it produces a fine amber-colored syrup is just now of more general importance than the fact—apparently established beyond a doubt—that it contains a paying amount of cane sugar. When those who have never before cultivated sorghum, learn how to raise it and to properly handle it so as to produce a superior article of syrup, a great point will be gained, and the farmer will then be prepared for the next step—the production of sugar. But we think it would be a great mistake for one entirely inexperienced to sow a large breadth to sorghum with a view to the production of a large amount of sugar. Go slow in this, as in all new things. Even in small quantities for syrup, the means of working up the crop should be thought of. But few are able to purchase a mill and evaporator for merely making syrup for their family use. If some one at no great distance is prepared to work up the cane for others, then it may be safely planted. If there is no mill in the neighborhood, then there should be co-operation. One farmer can procure an outfit, if several other farmers will raise enough cane to keep him at work during the season. Or several may unite to purchase in common. This matter should be determined upon well in advance, and the machinery ordered early, so that it may be set up and in working order well in advance of the harvest.

**Successful Farmers in Hard Times.**—An agricultural writer who has recently returned from a trip through the Eastern States says in an exchange: "A most noticeable thing in traveling among farmers is, that those who have held their own the best through the recent times are the ones who are the most progressive. By this I mean those who have been quick to see what was best adapted to their line of farming, and who endeavored to supply what the local demand called for. Such men have been the first to apply improved methods of cultivation and to cultivate well; to apply a liberal dressing of dung or chemical manures to their soils, knowing that it costs no more to cultivate a field which will yield a hundred-fold than one that will yield thirty-fold. If the prices are low the largest yield may pay a good profit, while the lowest means a serious loss."

**Lawn Mowers. — Pennsylvania — Philadelphia.**—We are not about to discuss the merits of these excellent mowers. Their makers usually set forth the superior qualities of their machines, respectively, in our advertising columns. But to have the maker of one mower advocate the merits of the rival machine is a novelty. Yet this is just what was done last month, when Messrs. Lloyd, Supplee & Walton were made to claim a high rank for the Philadelphia Lawn Mower, while in reality they are makers of the *Pennsylvania* Lawn Mower. The substitution of one name for another in this case is one of those unaccountable blunders that will sometimes occur with types—of course it is the fault of the types—and all we can do in the case is to state the fact that it is the "*Pennsylvania Mower*" and not the Philadelphia Mower that is made by Lloyd, Supplee & Walton, and that their machine has met with approval wherever it has been used. As to the Philadelphia Mower, its reputation is well established, and as every one knows is made by Graham, Emlen & Passmore, who will prefer to present its claims over their own name.

**The Poultry Standard.**—All who exhibit fowls are aware that the judging is—or ought to be—done in accordance with the American Standard of Excellence. This consists of a "Scale of Points" for each breed of land and water fowls, carefully considered and fixed upon by the American Poultry Association, and is by the authority of that body published in a book. At the Annual Meeting for 1880, held at Indianapolis, a number of amendments were made to the Standard affecting several important breeds. These have been published on a sheet as a Supplement, and can be obtained by sending a 3-cent stamp to the Secretary of the Association, Geo. S. Josselyn, Fredonia, N. Y.

**Portable Sweep Power.**—"W. H. S." A portable sweep power would not be nearly so convenient as a tread power, but any of the large dealers in agricultural machines, whose names appear in the advertising columns, could supply one. One is about as good as another, as they are all made on essentially the same principle.

## Bee Notes for May.

BY L. C. ROOT.

The success of the beekeeper for the season will largely depend upon his properly conducting the operations of the present month. Those who read these "Notes" are aware that I differ with most writers as to stimulating early breeding. I speak chiefly from experience gained in Central New York, and my advice is especially applicable to similar climates. Those in warmer or in colder localities must time their operations according to the difference in the seasons.

With us the Soft Maple blossoms about May first. This I find the most suitable time to remove bees from their winter quarters. As soon as they are placed upon their summer stands and have had a flight, honey will be uncapped and removed to the center combs. The queen will at once begin to deposit eggs, and a general movement will be made towards rapid increase. The beekeeper should be prompt to aid, in all possible ways, the securing of the large force necessary to gather the stores of honey which will be afforded, as the season advances. If the stock is reasonably populous and has a good queen, proper food and a good degree of warmth are the essentials to its rapid increase. If the number of combs to each colony was limited as directed in April, supply each hive with additional combs, as the strength of the swarm demands. Sometimes, in the best swarms, nice clean combs may be placed in the center of the cluster when the queen will occupy them more readily; but take care not to injure the swarm by spreading the brood too rapidly. As brood is now being extensively reared, large quantities of honey are consumed, and care must be taken that the supply is not exhausted. During this month, in many localities, the Yellow Willow, and Sugar Maple, will furnish sufficient honey to aid largely in the increase. The general bloom of fruit will closely follow the yield from these, which often affords a rich harvest, and brood-rearing will go on rapidly. Following the fruit blossoms and preceding White Clover, there will be a period in many localities when little honey will be gathered. Breeding may have gone on up to this point to such an extent, with so great a consumption of honey, that the supply of food may now be entirely exhausted, the result of which is more disastrous than beginners can appreciate. Breeding will not only be discontinued, but large quantities of immature brood will die for want of food, and be removed from the cells. If at any time this scarcity occurs, feeding is absolutely necessary. To sum up for this month: Do not remove bees from the cellar so early that the weather will be likely to hinder continued breeding. When once started, see that the entrance is small, that the warmth of the hive is retained, and that there is always a supply of food. Add empty combs, but only so fast as the strength of the colony requires. Never add more combs than the bees will occupy, as it increases the space that must be kept warm, which is not only unnecessary but harmful.

## QUESTIONS AND ANSWERS.

**FEEDING BEES TO STIMULATE BREEDING.**—"In the spring shall I feed colonies with syrup that have a good supply of sealed honey?".... "If at no other time, is it necessary to feed colonies having sealed honey, during the scarcity between apple blossoms and white clover?".... "Are weak colonies with an abundance of sealed honey benefited by feeding syrup?".... "To stimulate breeding shall I uncup unsealed honey?".... These are very practical questions. While I am an advocate of judicious feeding, if done under the direction of an experienced operator, yet there are so many chances of failure, if improperly conducted, that I hesitate to advise the average beginner to practice it under the above mentioned circumstances.

**STRENGTHENING WEAK COLONIES.**—"To strengthen a weak colony, or one that does not work in the boxes during honey gathering, will it be safe and a benefit to remove it to the stand of a stronger one, and thus exchange them?".... When bees are gathering honey very rapidly I have practised this with success. If honey is not gathered plentifully, it would be preferable to remove cards of brood from the stronger stocks, and exchange them for empty combs from the weaker ones.

**AT WHAT AGE TO DESTROY QUEENS.**—"Do you kill your queens when they are three years old?".... "Shall I not leave our queens just as they are, when by the presence of brood I know she is present?".... As a rule we do not rely upon a queen after the third season. Unless a close record is kept of the different colonies, it will be difficult to ascertain the exact age of all the queens. If we have a choice queen, we do not destroy her until we see signs of deficiency. Such queens as prove themselves prolific by a good quantity of brood, we would prefer to leave undisturbed.

**GLASSING HONEY BOXES.**—"Shall we put the glass in boxes filled with honey, as soon as removed from the

hives, or not until time to send it to market?".... For many reasons it is preferable to wait until ready to ship.

**SWARMS IN HIVES WITH COMB FOUNDATION.**—"C. W. N." asks, "In hiving a natural swarm in a hive filled with comb-foundation, would you put the bees directly into such a hive, or gather them first in a common box hive and transfer them in the evening?".... Have the bees in an empty hive just like the one containing the frames of comb-foundation. Then place the hive containing the foundation over the one containing the bees, and they will pass up into it, when the lower hive may be removed. This is preferable to waiting until evening and disturbing the bees a second time. If hived in this manner early in the day, a fine start will be made at comb-building. Comb-foundation used for this purpose should have wires incorporated with it to prevent sagging.

## The Weeklies' "Agricultural Column."

—The importance and the popularity of Agriculture in this pre-eminently agricultural country, is recognized by the newspaper press generally, by a maintenance of an "Agricultural Column." As a rule, these columns are a positive injury to the interest they would compliment, or even try to benefit, from the fact that those who edit—or rather "scissor" the contents, are not fitted by experience and education to do their work well. There are, if possible, more quacks among professed agricultural writers, than among medical practitioners, and these ambitions gentry have the faculty of setting forth their ideas, their whims, their crude theories, in a language and style that make them appear very plausible. Such items are quite as likely to go the rounds of the "Agricultural Column," as the cautious, careful teachings of well-informed, experienced, practical men. There are, however, exceptions to this general sweeping charge against the so-called "Agricultural Columns" of the weekly press, and the number of exceptions is increasing. First, are those who make up such columns, not from the usual floating deadwood or light wood, but only make their selections from the few agricultural journals of undoubted reliable and standard character. A few others go to the expense of securing the aid of men of acknowledged study and reliability to edit or provide material for such columns.—The above remarks were suggested for the moment, by noticing the series of articles on "Recent Developments on Dairying," by F. D. Curtis, Sec'y of the N. Y. Dairymen's Association, which are being issued from week to week in the "Northern Christian Advocate," of Syracuse, N. Y., whose agricultural, as well as other columns, are really edited with care and not at random, in the easy way, with "scissors and paste."

**The Corn Crop.**—The value of a corn crop cannot be fairly estimated by taking into the account the grain and fodder produced. It should be looked upon as a fallow crop, furnishing the opportunity for the thorough pulverization of the soil and the extermination of weeds in the labor required for promoting its full growth and development, while the raw manures that can safely be used will have an influence upon the soil that, the other more sensitive cereals will in their turn profit by. The manner in which manure should be applied will be determined by its condition and the economical disposition of the labor required in hauling and spreading.

**The New York Horticultural Society** is showing signs of renewed life in several directions. Its Monthly Exhibition, held on April 6th last, was so attractive that the room was so crowded as to suggest the need of a larger place in which to hold future monthly shows. We have recently received a copy of the essay read by Peter Henderson at the March meeting, on "Horticultural Progress," especially as relates to New York City. This interesting sketch is prefaced by a list of the officers and members of the Society, and all is produced in a style of such exquisite neatness that indicates rare good taste on the part of some one. We would again remind our friends that these exhibitions are held on the first Tuesday in each month, at 2 o'clock P.M.; all are welcome.

**"Stagger Weed."**—A Virginia correspondent writes that many horses and cattle die from eating a plant popularly known in his locality as "Stagger-weed." He sends a specimen which will, we think, soon flower, when we shall be able to determine what it is with certainty. Our correspondent resides in Tazewell Co., and the object of this note is to ask if a plant poisonous to domestic animals is known as "Stagger-weed" in other parts of the State. We are aware that there is a "Stagger-bush," but this is an herb that dies down at the approach of winter and comes up tender and succulent in spring. Any information concerning the effects and antidotes, if any are known or suggested, will be welcome.

**Increase in Value.**—Good Doct. Torrey in his lectures, as an illustration of the increase in value imparted to raw material by the processes of manufacture, used to compare the value of a pound of crude steel with

a pound of the hair-springs to watches. We have now forgotten the figures he gave, but were reminded of the incident by an item now going the rounds of the papers, which begins with 75 cents worth of iron ore. This amount of ore is said to yield \$5.50 worth of bar iron, which will be worth \$10 made into horse-shoes. Converted into steel it will make \$6,800 worth of needles, \$200,000 worth of watch-springs, \$400,000 worth of hair-springs, and if made into pallet arbors (which are parts of a watch) its value would be \$2,500,000.

**A Great Waste.**—It is the practice of many dairy farmers to kill the calves at a very early age, long before they can be—or should be, of any use as food. This is a source of loss, which, take the country through, is something enormous. An animal already grown to the weight of 60 to 80 pounds, and which might, through a few weeks of proper feeding, be made to yield a large amount of food, is killed, and all that is saved is the skin! There are cases when it is the best economy to get rid of the calves so soon as they come, but these are exceptional, and in the ordinary dairy of a farm practising mixed husbandry, there is seldom, if ever, a call for such an untimely and unprofitable removal of the calves. It will pay well in many cases to grow the calves until they are six months old, and thus produce an animal weighing 500 pounds, and of the best quality, commanding a ready sale in the markets.

**Improvement Through the Males.**—The only practical method of the means that is within the reach of the average farmer, of raising the standard of a herd of cattle, flock of sheep, etc., is through pure blooded males. A male of this character may be bred to a considerable number of females, and all of the offspring will be brought more than half way up from the level of the dam to that of the sire. The sire being pure bred, will have the greater power to fix his characteristics upon the offspring. If the qualities of the Ayrshire are desired, it is not necessary to buy a full herd of Ayrshires, but instead, a single pure blooded bull, and with ordinary stock a good herd may be produced, which will, year by year, by careful selection, become more and more desirable, and thus, in the course of a short time, a very valuable stock may be built up at a comparatively small cost.

**The Massachusetts Horticultural Society** continues its annual offer of special prizes for the best essays on various horticultural subjects. For 1880 a prize of \$50 is offered "For the Best Essay upon any Special Action of Fertilizers, illustrated by Accurate Experiments." A prize of \$25 "For the Best Essay upon Flowers for the Home, with lists of the Best Annuals, Herbaceous Perennials, and 'Bedding Plants,' and a comparison of the merits of these classes." These prizes are designed to bring out new and important facts upon the subjects chosen. "Competition is open to all." Further information can be obtained by addressing the Secretary, Robert Manning, Boston, Mass.

**Extreme Cold Endured by Seeds.**—Some recent experiments by DeCandolle and Pictet, of Geneva, are of interest as showing the great cold which seeds may endure without injury. Mustard and cabbage seeds and grains of wheat, without previous artificial drying, were enclosed in sealed tubes and subjected to a temperature of 50 to 80 degrees below zero Centigrade (80 to 100 of our ordinary Fahrenheit thermometer), for from 2 to 6 hours. These seeds afterwards germinated promptly and with a vigor equal to those not thus treated.

**Suggestions offered to Farmers** in a recent "Bulletin" issued monthly from the rooms of the New Hampshire Board of Agriculture: "Pursue a higher and more economical line of farming, by adopting a better system of breeding and feeding domestic animals; by a more thorough preparation of the soil, and increased tillage; by adapting products to the markets, or to economical consumption; by the use of machinery in all farm operations; by increasing the manure heap, and its better care and application, supplementing it by the use of chemicals and specific fertilizers as required by soil and crops; by a judicious rotation, and the sowing of crops in the most condensed form; in short, strive to secure the highest results from the least expenditure."

**Vegetation Retains Soluble Matter in the Soil.**—The April number of the "American Journal of Science" relates the following: "Soil three inches deep was placed in two glazed earthenware pans 17 inches in diameter, on July 21; for seeds of white clover were sown in one, the other being left blank. The pans were equally exposed until October 4, when the drainage water was collected and analyzed; that from the clover soil contained 48.1 grains of solid matter per gallon, the other 2.0 grains. The author concludes that rain removes much more matter from an uncropped than a cropped soil." We need more such experiments as these.

**Bad Cement.**—"J. Q." A cemented cistern should be left for a week or 10 days for the cement to set and harden, before the water is let in. If the bottom leaks after that, the cement must have been of poor quality. It would be well to empty the cistern, and give it a coat of clear cement, without any sand with it.

**Like Produces Like.**—Some years ago, we planted a number of hills with small potatoes, and by the side of them, an equal number with large ones. Both rows received the same attention; and on digging, the large "seed" gave  $3\frac{1}{2}$  times as many pounds as the small ones. Do not try to save the large potatoes, by planting the small ones; there is good reason why it does not pay.

**To Measure Corn in Bulk.**—"J. P. D.," Point of Rocks, Md. To measure corn in bulk, find the number of cubic feet by multiplying the length, width, and depth of the crib, or wagon box.  $1\frac{1}{2}$  cubic feet will make nearly a heaped bushel of ears, which is equal to half a bushel of shelled corn. A heaped bushel has 2,750 cubic inches, a cubic foot and a half contains 2,592 inches, but a bushel of ears will make a little more than half a bushel of corn, and the excess in this will about balance the deficiency in the measure.

**An Experiment Station in New Jersey.**—One of the last acts of the N. J. Legislature was to provide by law for an Agricultural Experiment Station, and in no State is one more likely to prove useful. Should the Governor approve of the bill, good work will be done.

**"Trimming Up" Evergreens.**—A correspondent in Troy, N. Y., writes: "On the place which I have purchased there are many large evergreens, and the foliage around the house is so dense that I wish to trim up some of them. When is the proper time to do it?"—There is no day in the whole year which is *proper* for doing that which ought not to be done, and trimming up an evergreen tree is one of those things. A Hemlock, Spruce, or Fir, with its lower branches upon the ground forming a pyramid of green, is a beautiful object. The same tree with its lower branches cut away, and its naked trunk exposed, is a forlorn object that has no more beauty than a hay-cock upon a bean-pole. Our correspondent should first make a careful examination to see if his object can not be accomplished by the removal altogether of some of the trees; this would be far better than to mutilate them. We have no doubt that to "trim up" several of the trees would give to the place a very different aspect, and one that will be very unpleasant.

**Letters that are not Answered.**—When one like "B. F. T.," Huntingdon Co., Pa., fills several pages with questions, covering not only the whole routine of farm management, but also asking advice as to whether he had better keep school in winter, or keep on the farm during that season, he cannot expect an answer. Occasionally a correspondent, like this one, quite misunderstands the duties of an editor. When one comes across some difficulty in his farm work, is in doubt whether it would be better to follow this or that course, and wishes advice in the matter, it is very proper for him to state his case and ask our advice. But when a novice in farming asks a long string of questions to which a year's experience on a farm would teach him the answers, he must not expect us to write a treatise on general farming for his benefit. Take the letter in question. We see but little that is not sufficiently met by our "Notes about Work," take the season through, and on several of the topics there have been special articles. More than this, our correspondent wishes us to tell him what it would cost per head to transport cattle from his place to market. We could write to the master at his depot and ascertain, but it will be much easier for him to apply in person.

**Commission Merchants.**—It is rarely the case that one who raises fruits and vegetables, is also the one who sells them to the consumer, and it is an absolute necessity, especially with produce raised a long distance from the place of sale, that there should be parties who make it their business to sell it. The raising of fruits and garden truck is easy enough, the proper selling of the produce is not so easy, and the success of the grower, depends largely upon the seller. There is probably no business in which there are such ample chances for disagreement, and dissatisfaction, as that of the produce commission dealer. When all is managed with the strictest integrity, guided by the best judgment, the "returns" may fail to be satisfactory to the grower, who changes his commission man, only to fare still worse with the new one. Among growers, the commission men have a bad name, yet there are in that business men just as upright, and as honorable, as are to be found in any pursuit. Then again, there are others who would be described as "on the contrary quite the reverse." The business is one which offers peculiar inducements to swindlers and sharpers. It can be carried on, for a while at least, with very little capital. The articles come to

them on credit, and are sold for cash. Many a grower knows to his cost, that there are 'bogus' commission dealers. To those who write us about this or that person who wish their consignments, we must give the advice not to ship a single package to one who can not refer to well known persons as to their business standing. As the peach season approaches, the peach districts are infested by persons representing themselves to be commission merchants, and offering great inducements to peach growers to consign to them. As a general thing, these fellows have no location, and if they do any business, it is as squatters somewhere on the sidewalk. We can only say to enquirers, that by taking proper pains, they can find commission merchants of good repute. When dealings are commenced with one, do not change upon any slight provocation. It is a part of the business to have disappointments, and no human foresight can prevent losses on perishable articles, if they reach the market when it is already glutted.

**Horticulture in Nebraska.**—Nebraska carried off the prize from all other States for her fruit several years ago, and she deserved it. The State has always taken an active interest in fruit-culture, and it now keeps it up, as we see by the programme of a meeting of the State Hort. Society held at Lincoln in January last. Liberal premiums were offered for winter apples and pears, and also for flowers, and a number of interesting addresses were given. The State is divided into six fruit districts, and reports were made from each. The prominence of Nebraska as a fruit-growing State is largely due to the efforts of this Society, and the success of the Society is largely due to the active interest of its President, Gov. R. W. Furnas.

**Plowing.**—The character of the soil; the crop to be grown, and the kind, and amount of manure to be applied, are all factors which determine whether the plowing is to be deep or shallow. Light soil needs shallow plowing, and heavy soil with much vegetable matter, does best when plowed deep.
